I have the honor to be

Sir,

Your most obedient Servant,

JAMES R. WALLACE, M.D.,
Secretary, Indian Medical Association

7. The Secretary laid on the table an artistic design of the *CERTIFICATE OF MEMBERSHIP* for the Association, which, after great care and thought and the criticism of various talented artists, had been decided upon as a suitable form of certificate. The Council expressed their approval of the design, and gave the Secretary authority to order its execution.

8. Upon the representation of the Secretary to the Council, of numerous letters received by him from Civil Apothecaries complaining of their grievances, and requesting the Association to move the Government of India on their behalf, it was resolved that the Secretary do forthwith prepare a draft letter on the subject for early submission to Government by the Council.

9. The petty bills of the office being passed for payment, the meeting was brought to a close.

COMMENTS AND NEWS.

MEDICAL BLACKMAILING AND SCANDALMONGERING EXTRAORDINARY.

We quote from the *New York Medical Record* :—

"A long dispatch from London, published in the *Sun* a few days ago, brings into prominence what seems destined to lead directly to the culmination of the feud that has cropped out every now and then between MR. LAWSON TAIT, the great Birmingham surgeon, and some of his professional brethren belonging in London, particularly MR. ERNEST HART. It is in the form of a pamphlet to the publication of which DR. CUSHING, of Boston, seems to have innocently spurred MR. TAIT on by publishing the following statement :—In the light of facts recently placed on evidence concerning TAIT, his statistics have far less weight with the surgical world than was the case a year or two ago."

"MR. TAIT wrote to DR. CUSHING to ask what the facts were to which he had alluded. In reply, DR. CUSHING rehearses a scandal to the effect that MR. TAIT had seduced one of his nurses, and then, after having pledged himself to support the illegitimate child of which he owned to being the father, refused after a time, to continue such support. MR. TAIT then wrote back denying the whole story and impugning its relevance. In the course of this letter MR. TAIT says :—

"As to the story, it is a lie, or rather a tissue of lies, from beginning to end. Two women, sisters, entered into a scheme to blackmail me; one a nurse dismissed for insubordination, and one on whom I had done ovariectomy, and they had claim to £16,000 as hush money. They never got a shiver of that money, and the case never came to trial for the reason that you will see in the published account of it which I inclose. The case never came to trial, never a scrap of information appeared in the public press, much to my discomfort, but the plaintiff's story was spread abroad as a means of coercing me to pay hush money, and chiefly by members of my own profession residing in London. I stood firm to fight, as, unfortunately, too few men, placed as I was, do. The plaintiff's traded on the belief that a man in my position and as rich as I was, would pay up rather than have my name tarnished. But I would have spent my last shilling, and my wife would have sold her wedding ring, before I would have been bled in such a way. The case collapsed after nearly two years of legal dodging, and I never had an opportunity of proving the utter falseness of the charges made against me. Your informant may not have known this, but I suspect he did. Dates would prove this."

"MR. TAIT inclosed a photographic copy of the witness's retraction, duly witnessed, as follows :—I unreservedly withdraw all statements and suggestions at any time made by me or on my behalf that you ever assaulted me or took advantage of me in any way while I was under the influence of liquor or under any other circumstances. And I also unreservedly withdraw all other charges, imputations, and reflections at any time made by me against you."

"DR. CUSHING, thereupon, as in honor bound, gave MR. TAIT the name of his informant, who turns out to be MR. ERNEST HART, the editor of the *British Medical Journal*, now in India, and loyally offered to make any apology that MR. TAIT might require, and to give his testimony, if necessary, even in an English court. When MR. HART gets back to London we may perhaps be told how such a monstrous scandal got afloat."

THE EXAMINATION FOR THE L. S. A., LONDON.

We quote for the benefit of our readers the following questions for the Final Examination for the Triple Qualification in Medicine, Surgery, and Obstetrics, or the L. S. A., London, which is the only single diploma that qualifies for admission into the A. M. S. and I. M. S.

Medicine.—1. What are the consequences to the heart, recent and remote, which follow upon rupture of one of the aortic valves? What symptoms and physical signs would be found in such a case a year after the accident to the valve? 2. How would you investigate and decide upon the nature of a case of slight general dropsy? 3. Describe a case of acute suffocative bronchitis in a young adult. What physical signs would be presented by such a case? How would you treat it? 4. What symptoms and physical signs would be likely to be found in a case of granular disease of the kidneys? What are the chief dangers to life attending this condition? 5. Describe a case of tubercular peritonitis in an adult, its access, progress, and course. What other conditions of disease might such a case resemble, and how should the diagnosis be made? 6. Give the diagnosis between general paralysis of the insane, and disseminated sclerosis.

Therapeutics.—1. Write prescriptions containing, respectively (a) arsenious acid; (b) antimony potassium tartrate; and (c) carbonate of iron. 2. What are the ordinary therapeutical uses of belladonna?

Pathology.—1. What is an infarct? What are its local effects? 2. What pathological lesions are commonly associated with ADDISON'S disease? 2. What structural alterations are generally caused in the lungs and liver by long-standing obstruction of the mitral valve? Describe the microscopic appearances of the liver in such cases.

Surgery.—1. Describe the varieties of psoriasis, and the treatment to be adopted. 2. What are the positions in which fracture of the pelvis may take place? State the signs which may be present, and the treatment in each case. 3. How would you recognize the presence of fluid in the peritoneal cavity? Differentiate between that condition and ovarian tumours. Describe the operation of paracentesis abdominis. 4. Describe fully the course of development of a psoas abscess; give its signs, symptoms, diagnosis, and treatment. 5. Describe a case, in which the presence of gall stones necessitates the operation of cholecystotomy.

Surgical Pathology.—1. How do you explain the presence and growth of the several varieties of loose bodies which occur within joints. 2. Describe the changes which occur in the tissues affected in CHARCOT'S disease.

Anatomy.—1. Describe the operation of ligature of the common carotid artery, and enumerate the anatomical by which the circulation is re-established. 2. Mention the lines

of the bone, and the structures cut through in removing the upper limb, with the scapula from the body.

Midwifery.—1. A woman has been many hours in labor; the membranes have been ruptured a long time; she complains of sudden pain in the abdomen, and is seized with faintness; there is slight bleeding. Discuss the nature of the case, and the treatment you would adopt. 2. Describe the various methods of artificially feeding an infant a week old. 3. Discuss the etiology, pathology, symptoms, and treatment of puerperal eclampsia. 4. Describe the mechanism of labor in occipito-posterior positions of the vertex.

Gynecology.—1. Describe the healthy secretions met with in the female genital canal, and the alterations they undergo in disease. 2. Describe some of the commoner causes of suppuration in the female pelvis, giving the differential diagnosis and treatment.

Forensic Medicine, Hygiene, and Insanity.—1. Describe the symptoms and treatment of acute poisoning by antimony, and state in detail how you would use MARSH'S test. 2. Define and give examples of a delusion, an illusion, and an hallucination, respectively. 3. What measures would you employ to prevent the spread of diphtheria in a school in which some cases had occurred? 4. A corpse is found in a canal with a contused wound on the head. How can it be determined whether the injury, or drowning, is the cause of death?

OPHTHALMIC SURGERY IN INDIA.

As an evidence of the very large amount of ophthalmic work occasionally done in a village district of India, we may place the following on record. The *Lancet* writes "A few weeks ago, Surgeon Lieutenant-Colonel G. C. HALL, F.R.C.S., Eng., surgeon to the Allahabad Eye Hospital, was called upon to operate on a patient in a village in the province of Oudh. The village was some twelve miles from the railway and twenty-six miles from any English station. No means were taken to let the people in the surrounding villages know of the intended visit of an ophthalmic surgeon to their neighbourhood, but the news nevertheless spread. Surgeon Lieutenant-Colonel HALL lived in camp. The natives arrived in various ways—some in bullock carts, having been four or five days on the road, from distant villages; some came on foot, led by others not quite so blind as themselves; others were carried on the backs of their relatives. A large number had no eye left to be dealt with, but all had a large amount of faith. It was altogether an extraordinary and weird spectacle to see these poor helpless people coming into camp in the early morning and quietly sitting down in groups patiently waiting until their turn came. During six days the total number of patients seen was 894, the total number of cataracts extracted 69, and the total number of operations performed was 147. The operations were all done in the open air under the shade of a large mango tree, the patient lying on a native bed, the operator sitting at the head of it. As far as possible, all the cases were treated antiseptically, and notes were taken of them, with the prognosis formed at the time of operation. When Surgeon Lieutenant-Colonel HALL left, which he did on the sixth day, a native assistant remained to look after the patients, to whom sixty-five pairs of spectacles have already been forwarded for the successful cases. We think our readers will concur with us in considering that the foregoing account records an enormous amount of hard and successful work of a most humane and philanthropic kind, of the accomplishment of which any one may well feel proud."

THE FISH SUPPLY OF CALCUTTA.

MORE than half of the fish eaten in Calcutta is obtained from that huge network of tidal creeks, swamps, *shals*, *jungle* and bunds known as the Salt Water Lakes, a region occupying some 30 square miles, stretching from Dum-Dum to Garriah, and contains the "square mile" where the Corporation of Calcutta "dumps" the street sweepings and garbage of this town. Through this "square mile" flows the hideous canal that carries the night-soil of Calcutta and its suburbs into the Gurriah tidal creek. Round about Katatollah, a large fishing village at the edge of the Sunderbunds, exists a very Golgotha of bones, shells, fish-bones and all manner of rotten abominations in every stage of decay; but furnishing enormous wealth in the shape of shell-lime and agricultural phosphates. This entire tract is leased by a *Kuruman* family, who have sublet portions of it to hundreds of *jellahs* (native fishermen) who are actively employed in trapping the fish by net, weir, spear or hook, and then taking their captures to Chingrihatta and Balliaghatta, whence they find their way to the Calcutta markets. The Bhagirathi, Jellingi and Matablauga rivers add their quota, and huge quantities of fish are also brought by rail from Goalundo. Enormous quantities that cannot be immediately used are salted down, dried or cured in tamarind, prior to being sent to market. The prawn and crab supply comes entirely from the lakes and tanks, and lobsters from the rivers; while some of these crustaceans are obtained from very doubtful sources. There is not a single species of fish, hooked, netted, speared or dug out of clay, which is not eaten by the natives, but luckily no poisonous species are found in the rivers, swamps or tanks of Lower Bengal. It may also be remembered that large quantities of fish are recovered from the fresh water tanks of Calcutta, where they have been propagated from "fry" caught in the districts above alluded to.

THE INSANITARY BOARD OF MADRAS.

MADRAS has always been unique for anomalies and administrative curiosities, but whenever it indulges in its love of singularity, it contrives to be in the wrong. Till lately the Madras Board of Sanitation consisted of two members: The Sanitary Commissioner (DR. KING) and the Sanitary Engineer (MR. JONES). The former complained to the Government that the latter never consulted him in sanitary matters, nor informed him of any such schemes having been proposed or being in course of execution, but "left him to ascertain the nature of such works as best he may from the public prints or during his inspection tours from such few papers as may incidentally have been communicated to the public bodies concerned, to whose courtesy he is indebted for their perusal." DR. KING furthermore complained that he was deliberately kept in ignorance of the very existence and issue of many important matters, and that even "Government orders on sanitary engineering matters" of sufficient public interest to be "placed on the editor's table" were not sent him for perusal. Madras slept over this complaint and perhaps would still be sleeping, but commenting on this deliberate ignoring of the *senior* member by the *junior* member of the Sanitary Board, the Government of India thinks that the Sanitary Engineer should work as much as possible in concert with the Sanitary Commissioner, without whose knowledge no project should have been submitted to Government, and as the former Board has not in all respects fulfilled the expectations that were formed of it, the Government considers that it would be strengthened by the addition as President, of the Chief Engineer, Public Works Department.

RUBBISH INCINERATORS.

FIVE years back, MR. HARRINGTON persuaded the Calcutta Municipality to erect the huge columns, that over-topping everything else in its vicinity half poisoned the neighbourhood, by the dense columns of noxious smoke it vomited forth and showed its utter incompetency to effectually deal with Calcutta's indescribable rubbish. Subsequently another incinerator was run up at the edge of the salt marshes, where the results obtained, though not quite perfection, are somewhat more satisfactory, and MR. HARRINGTON contemplates improving upon his method with a view to more perfect combustion, less smoke and noise, and set in place of the clinker now obtained. At Bombay excellent results have been obtained from MR. GARVIN's pattern, in which an engine, driven by the burning rubbish, maintains a forced draught and practically no clinker is produced. The GARVIN, whose special claim is the incineration of human faecal matter, is being experimented upon at Umballa. If India is to be served by incinerators, something less expensive than the English type of apparatus must be contrived, declares *Indian Engineering*, and we concur. The GILCHRIST is so far the cheapest, as it requires no forced draught, yet effectually deals with the rubbish and effects matter of 2,000 persons, *per cell*, and each cell costs only Rs. 480. MR. ROBERTS of MESSRS. RUEN and Co. seems to be on the right road to combining economy and worth, as the incinerator at *Honorah* has so far given the best results towards absolute combustion of the rubbish and destruction of the more noxious of the gaseous products of combustion obtained by any of the apparatus hitherto experimented on in India.

BACTERIOLOGICAL INVESTIGATION IN INDIA.

IN a lengthy letter addressed to the Government of India, MR. ERNEST HART deplors the want of bacteriological work in this country, and while deprecating the insane system of vesting two kinds of duties requiring very different kinds of knowledge in one and the same person, points out that the whole theory of official life in the British and Indian services is *entirely* adverse to the conditions of scientific research and the mobility of research essential to the efficiency of laboratories. Urging the absolute necessity for bacteriological investigation as the *only* means of determining the origin, methods of diffusion and measures for the prevention of any local outbreaks of cholera, typhoid or epizymotic diseases of man and other animals, he finds fault with the present system of monopoly, and suggests that the persons to be appointed as superintendents of such laboratories should be *preferably* selected from civil life than from the Army Medical Services, which latter complain of already being over-worked and to remove any of them for bacteriological work, means to throw the weight of their legitimate work on to the already over-burdened shoulders of those remaining.

We do not quite understand the reason for the sudden and opposite change in MR. HART's tactics, but if he is sincere in what he now writes, we congratulate him on having discovered the truth, and heartily endorse his plea for the necessity of wholesale reform.

**"IS THE CODE OF PROFESSIONAL ETIQUETTE
BETWEEN MEDICAL MEN OF ANY
ADVANTAGE TO THE PUBLIC?"**

Science Gleanings has the following excellent answer to the question:—"Yes, it is certainly a very fortunate thing that the general body of medical men are agreed to hold themselves bound by an exceptionally strict code of business 'ethics,' for only in virtue of this fact is it that the science of physics becomes continually associated with new accounts

of the deaths and other losses that result from ill-considered surgery or dosage. But by an *original* proceeding in the world such defects (probably more patent to him than to others), as might develop themselves in a structure, for which he was responsible. If indeed, that sort of thing were done it might prove a vast benefit to engineering science; but in the meantime the individual would be ruined. On the other hand, in the medical world, professional men are mutually agreed that failures, which must be so very common to all, shall—excepting for the clinical lessons that they teach—be honorably ignored. Hence it is very seldom that these reports on cases, with which technical medical journals are filled, appear to be so warped and rose-colored as the uninitiated world expect. Truth prevails, simply because medical etiquette ensures that personal interests shall not be opposed to it. Thus medical science is improved, which is of the greatest advantage to the public."

LADY DOCTORS IN INDIA.

UNDER the *nom de plume* of "VIOLET," is published an interesting article, wherein a contemporary avers that while the lady doctor is a God-send in zenana practice (where a male physician would not be admitted), and has done and still does a great deal of "good," she is frequently subjected to supercilious and overbearing treatment from the husbands of her patients, as being a woman they seem to think she is not entitled to the respect or courtesy they would extend to a man. Again, when in charge of a dispensary in the pay of zemindars or a "company of native merchants" she is treated as a menial servant, and efforts are made to exact more than the pay entitles. Lastly, she complains that when a lady doctor is sent to take charge of a hospital in a station which already has a Civil Surgeon, the latter, instead of working harmoniously with her, interferes with and retards her duties. There are some exceptions, however.

SOME ADVERTISING TRICKS.

THE *British Medical Journal* takes exception to an advertising method which has lately been adopted by the National Orthopaedic Hospital, Great Portland Street, London, which has issued a pamphlet appealing for subscriptions and containing woodcuts illustrating the condition of patients before and after treatment in the hospital. The Bristol Hospital for sick children and women has offended similarly in issuing pictures of a little boy before and after an operation for talipes. It is satisfactory to find that these procedures have been adopted without the knowledge or consent of the medical staff of those institutions. The dignity of the profession or the feelings of its members appear to be not at all considered by hospital Secretaries and Committees in their endeavours and desires to further the interests of their institutions; and the result is the adoption of measures which tend to defeat the very objects they were intended to effect.

THE HEALTH OF CALCUTTA.

The small-pox scare continues though there is a distinct subsidence in the epidemic, the death-rate having fallen from 186 to 140. Cholera is still largely present, and a mild form of epidemic influenza as well as measles, afflicts the town. The heat is very trying, and it is reported that a number of cases of typhoid fever have broken out among the European population. The general death-rate is still exceedingly high. It is very probable that the whole question of the sanitation of Calcutta, which is causing much public agitation, will soon be thoroughly thrashed out by the Municipal Commissioners.

THE MEDICO-SURGICAL TREATMENT OF FACIAL BLEMISHES.

Evening such, the gentle sex may be charged with being really vain and keenly solicitous for the improvement of appearance, or for the upkeeps of their charms, there can be no doubt but that the falling is common to mankind in general. We think, therefore with Dr. E. H. SCHWARTZ of Kansas City, that it is surprising that the subject of removing facial blemishes and of improving the appearance of the skin of the face should remain more or less resigned by the profession to the makers and readers of proprietary remedies. While the aims of medicine have always been not only to relieve pain, but to remove or mitigate personal defects, it has allowed those anxious about their personal appearance and desirous of soft, smooth, velvety skins scarce any other alternative but that of resorting to dangerous ranges, useless cosmetics, &c., for the attainment of their object. We think that nothing will be found so remunerative in the profession than the study of facial dermatology and of the science and art of cosmetics.

A LEGAL VIEW OF PROFESSIONAL SECRECY.

COMMUNICATIONS made by a patient to his physician are in Indiana strictly by statute forbidden to be disclosed. A physician sued for failing to treat a hip-dislocation properly was accordingly prevented at the trial from referring to several matters relevant to the case, and which occurred at an examination of the case with a consultant; and damages to the extent of 1,500 dollars were allowed the patient. On an appeal being made, however, it was decided that communications made to a physician were forbidden to be disclosed except with the knowledge and consent of the patient, and that when the patient sued the physician for secrecy in regard to any circumstances connected with the case, and its treatment was no longer to be demanded of the physician. The physician's examinations and the consultation were all for the purpose of curing the patient, and it will be unfair to allow the patient to select what circumstances suited him only, and to thus limit the physician's testimony. All matters bearing on the case were therefore received in evidence.

ASSISTANT SURGEON JOHN A. KELLY, I. M. S.

WE deeply regret to announce the untimely death in London, from influenza, of Military Assistant Surgeon JOHN A. KELLY, L.R.C.P. & S., Edin., F.R.S. London. DR. KELLY was one of the most promising Eurasian graduates of the Madras University, of which he held the degree of L.M.S. He was the Hobart Prize man of his year, and was appointed lecturer in materia medica and chemistry in the Hyderabad Medical School. Subsequently he went to Edinburgh and obtained the diplomas of the Royal Colleges of Physicians and Surgeons of that city. After a few years of further practical work and study at Hyderabad, he recently went to England to graduate M.D. and F.R.C.S., and there can be no doubt that success would have crowned his efforts, for he was a man of sterling qualities and a linguist of no mean order, having passed the higher standard examination in Hindustani, Persian and Tamil.

REST AFTER SUDDEN GRIEF.

DR. LOUIS BAYSON urges that rest and temporary seclusion are absolutely necessary for the nervous system after blows caused by sorrow. To try and find relief in work, study or amusement, is useless and dangerous. Grief cannot be ignored nor can it be checked up; and rambles in the open air, sea-side solitude, quietest drives and the companionship of children have soothing influences. Seclusion, rest, sleep, appropriate food, fresh air, sunshine, interest that tax neither mind nor body, are the requirements in this class of illness. So reports the *N. Y. Medical Record*.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

We have pleasure in publishing the names of the following gentlemen and a lady who have joined the Association since our last issue:—

G. Ram Kristna, G.M.S., H. H. the Nizam's Service, Deodrug, Hyderabad, Deccan.
G. Srinivasa Ram, G.M.S., H. H. the Nizam's Service, Yakootpura Diary, Hyderabad, Deccan.
C. B. Narasinga Rao, G.M.S., Hosp. Asst., Kolar.
Miss Louise B. Smith, G.M.A., Cal., 37 Dharwad St., Calcutta.
W. F. O'Connor, Assistant Surgeon, I. M. S., Sudder Hospital, Amballa.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

QUININE IN CHOLERA.

DR. ERSKINE FULLERTON, of Ohio, puts his faith on the value of quinine in cholera; and so much is he convinced of the efficacy of the drug in this disease that he does not see why the mortality from this disease should not be reduced to 5 per cent. and under in the United States. We do not know why DR. FULLERTON expects such happy results from the treatment he advocates in the United States only. Perhaps DR. FULLERTON does not mean it to be inferred that he places any geographical limits to the efficacy of the quinine treatment. His plan is to give ten grains of quinine in a small quantity of water or in acid solution at intervals of one hour, until twenty to forty grains have been given: the same doses half-hourly in collapsed cases, and smaller doses at longer intervals in choleraic diarrhoea. The medicine is said to be rarely vomited, and the administration should be begun early. As however, many other advocated remedies are directed to be employed in conjunction with the quinine we cannot estimate its importance as a curative factor.

ENQUIRY INTO THE "PHANTOM KISS" CASE.

WE rejoice to find that the proceeding of the Madras Government condemning to social degradation and departmental ruin of Surgeon-Major F. CLARENCE SMITH is at last likely to be officially examined and considered. The Major has been placed in possession of the charges against him, and we may expect to be soon told whether or not the doctor's delinquency, which has so seriously roused the moral sensitiveness of the Madras Governor, is regarded by the highest tribunal of the empire as deserving of the extreme punishment most arbitrarily awarded. The WENLOCK administration has been a quinquennium of unpleasant notoriety in many respects, and the SMITH kissing case is one of these. On the motion of MR. CAINE, however, in the House of Commons, MR. FOWLER has given promise to carefully consider a lengthy memorial received from DR. SMITH, and we hope that ample justice will be done to DR. SMITH and to those who have subjected him to serious humiliation and grief.

HOW TO IMPROVE INDIAN VILLAGE SANITATION.

"X," writing to *The Englishman*, proposes the following means of improving village sanitation:—

"In such villages as are able to pay, and in which one or more families of the scavenging class are to be found, the people may be assessed a pie a head; the sum thus collected

being paid to a scavenging family of the village, which will in return be required to perform such small duties in aid of sanitation as may be imposed on them, under the immediate control of the panchayat or a responsible agent otherwise provided; or several such villages may be grouped into circles under local or district boards. The suggestion is well worth a trial, and has the merits of being both cheap and easy of application."

SHORT ITEMS.

The rule still holds that the widow of a medical man is entitled to much consideration and if need be, to gratuitous medical attendance from the profession. The rule is not an absolute one. It is subject to considerations of reason and circumstance, and should not be pressed too rigidly on either side; but subject to these qualifications, it is one to be respected.

It has been ruled by the General Medical Council of Great Britain that the term "skilled midwife competent to attend natural labor," when used in a certificate, is open to legal objection and is a contravention of the Medical Act. Will Indian hospitals granting such certificates to *dais* and midwives, please take note of their past transgressions?

When artificial respiration, friction and all the usual procedures failed to revive a newly-born infant from apparent death after delivery with forceps, M. Guet tried *rhythmical tractions on its tongue* for six minutes with such marvellous success, that he commends it to the notice of *accoucheurs* as being superior to all other methods for restoring life.

A large gall-stone weighing 250 grains, was removed by Dr. T. A. McGraw from the junction of the jejunum and ileum, where it completely filled the lumen of the intestine of a patient who was operated on for obstruction of the bowel.

The verdict of the Leprosy Commission, that leprosy is a non-contagious malady, is practically rejected, for the principle on which the Leper Act passed by the Bengal Legislative Council is based, is that leprosy is a contagious disease.

Efforts are being made by the Mukherjees of Uttarpara for the establishment of an Ayurvedic Institution in Calcutta to give regular and sound training in the Ayurvedic system of medicine. A hospital and garden are to be attached to it for the growth of medicinal plants.

The Sanitary Board at Hong-Kong have decided to discountenance any sanitary policy that contemplates sewage-drains from Chinese houses. The hand-system of sanitation is to be maintained and extended as in every way safer to public health.—*Indian Engineering*.

The *Morning Post* records a case of snake-bite in which the patient recovered by the prompt application of a ligature above the bitten part, and six leeches, which sucked the wound and died as they fell off.

The Calcutta Health Officer is being soundly rated by the Indian press for devoting his whole time to microscopic, editorial and congressional work, instead of looking after the scavenging of the city.

The threatened strike among the milkmen of Calcutta has commenced in the totally suburban area of the city, and unless the Municipal authorities relax the now rules for the regulation of cattle sheds, the strike promises to be general.

Dr. Panlery, Assistant Surgeon of the Calcutta General Hospital, has obtained three months' leave to assist Dr. Moosatha Nath Chatterji, Resident Physician of the Mayo Hospital, will officiate during his absence on leave.

Any case of epilepsy developing suddenly in a patient who has passed thirty-five years of age, and who gives no history of injury, Prof. Hare says, is almost invariably caused by syphilis.—*Practitioner*.

The headaches of pregnancy, if persistent, should always be regarded with suspicion. They too frequently give evidence of uræmia and threatening eclampsia.—*Glasgow Med. Jour.*

Twelve natives of Manicktollah, Calcutta, were prosecuted before the Deputy Magistrate of Sealdah for refusing to vaccinate their children, and were fined from Rs. 12 to Rs. 15 each.

The investigations of STRAUSS have conclusively shown, that the nasal cavities of healthy persons who frequent localities inhabited constantly by phthisical patients, can be, and often are, infected by virulent *tubercle bacilli*.

According to a new law passed by the New York bureau \$5,000 is the extreme amount that can be claimed as damages by the relatives of a person who is killed through the negligence or carelessness of another person or of a corporation.

Surgeon-Colonel D. F. Bateman, I. M. S., P. M. O., Mandalay and Chin Hills command, has been directed to proceed to Madras to join his new appointment.

Monghyr is to be supplied with drinking water from the hot spring in the adjacent village of Sitakund. The District Board are acquiring land for the purpose.

The Senate of the Glasgow University has conferred on Surgeon-Major L. A. Waddell, M.B., I. M. S., whose researches in Sikkim are so well-known, the Honorary Degree of LL.D.

Miss Lillian Hamilton, M.D., accompanies the Amir's son in her medical capacity. We wonder how this anomaly was permitted!

If you have a fatiguingly deaf patient to talk to, place the ear-pieces of your binaural stethoscope in the patient's ears, and talk into the chest piece, and you have an excellent ear-trumpet.

If you leave your spectacles at home, being old and apyopic, make a hole with a pin in the corner of your visiting card, and you can read your clinical thermometer or anything else.

Khan Sahib Amir Buksh, Hospital Assistant, Viceroy's Dispensary, has been selected to accompany the Amir's son home, as native doctor.

Four villagers have been sentenced to death for the murder of Dr. Ranjeet Sing, and ten others, who were also implicated, have been discharged by the Sessions Judge.

New dissection rooms are soon to displace the present disgraceful structures in the anatomical department of the Calcutta Medical College.

Surgeon Lieutenant-Colonel E. C. Duff, M.B., I. M. S., officiates as professor of materia medica, vice Professor McConnell, who goes on leave for six months.

Colonel Sir James Lindsay and Surgeon-Major George Scott Robertson, M.C., I. M. S., the British Resident, is safe but has been slightly wounded.

Dr. Salmon, of Cowbridge, has just attained his 108th year. He is the oldest Freemason in the world, and was a surgeon in the army of George III.

The degree of L. L. D. of the Aberdeen University has been conferred *honoris causa* on Surgeon Major-General Robert Harvey, M.D., F.R.C.P., D.S.O. of the Punjab Army.

Surgeon-Colonel W. F. Burnett, A. M. S., has been appointed P. M. O., Mandalay and Chin Hills command.

Christopher Heath, F.R.C.S., Eng., has been elected President of the Royal College of Surgeons of England.

Cholera of a virulent type has broken out in the Dum-Dum Cantonment. Several deaths have occurred.

Surgeon-Major Westcott has gone from Hong-Kong to Hainan to investigate the alleged existence of plague there.

Current Medical Literature.

MEDICINE.

The Signs of Heart Failure in Fever.

AFTER examining hearts of a great many patients who had died from varioloid and from typhoid fever, HAYEM noticed symptomatic myolitis, and attributing the alterations of the muscles to changes both in the blood, and the blood vessels stated that myocarditis was more marked in typhoid fever than in variola, and that in typhoid the changes in the heart are often limited to the arteries while the muscular fibres sometimes undergo vitreous degeneration. STREDEY fully endorses this view; but HUGHARD who studied these conditions with DESNOS declares that the fibres in myocarditis were much more deeply changed in variola than in typhoid and agrees with BERNHEIM that in typhoid the nervous element should be added to the myolitic, as the poison of typhoid acts on the heart like digitalis, and many of the symptoms attributed to myocarditis of typhoid fever must be referred to lesions of the cardiac nervous system or to the effect of functional disturbance, and injections of caffeine or of ergotine, and even cold baths should be employed in preference to digitalis when cardiac symptoms complicate typhoid. SAMPSON shews that, *la grippe*, much resembles typhoid as determining myocarditis, but causes other disturbances of cardiac innervation. HUGHARD, who points out that very great errors are often made in the diagnosis of acute myocarditis in fevers, especially typhoid, explains that while considerable myocardial lesions often appear in cardiac sclerosis, very grave symptoms of heart trouble were often accompanied by hardly any appreciable lesions of the muscular constituents of the heart. He furthermore insists that the signs of heart failure in fevers should not be limited exclusively to the determination of the weakening or the disappearance of the first sound, as besides this weakening there are two other symptoms: the embryocardiac and the broad diastolic, or prolongation of the cardiac diastole.

Is Simple Stricture of the Rectum in reality Syphilitic?

A white, pale, cachectic man, 45, complained of a swelling of the anal orifice which Dr. LAURENCE diagnosed as simple submucous stricture and opened by thermocautery. Patient progressed well till the 30th day, when a thin serous

discharge appeared, accompanied by sharp pains in the anorectal stricture, difficult defecation, tympanitic abdomen, general debility and loss of appetite. Further examination disclosing the presence of an ano-rectal gumma with stricture of the rectum, and the man confessing to a penile chancre and secondary syphilis in 1888, he was placed on specific treatment which brought about a rapid cure. M. FOURNIE, with whose views on this subject M. LADARRO fully concurs, contends that simple or fibrous rectal stricture is always syphilitic; and regarding this case as confirming his views, calls attention to other cases where with a rectal stricture, exist ano-rectal and ano-perineal lesions of a gummatous nature, and when these lesions are neglected, they may develop the regular anal fistula, which professor TRELAT described as syphilitic fistula.

Snake-bite treated by Injections of Strychnine.

DR. M. PERCIVAL, L.R.C.P., Irel., relates a case of snake-bite treated by strychnine hypodermic injections in the *Lancet* of 23rd March 1896. The man was brought to him four hours after he had been bitten; the appearances presented by him at first were extreme pallor, straggling gait, a cold perspiration all over the body, pupils widely dilated, pulse rapid, irregular, intermittent and barely perceptible, breathing in sighs, and giddiness. Marks of a bite were visible on the lip. The treatment consisted of two rapid injections of $\frac{1}{10}$ grain strychnine within 10 minutes, whereby the pulse improved markedly, a third injection was given, with the result that the intermittency ceased and the pulse came down to 96. Injections of $\frac{1}{10}$ grain were continued every 20 minutes, and pulse and breathing improved, the sweat vanished, but vertigo remained. He then had a relapse, but on further injections and assuming the recumbent posture, the patient rallied and was admitted into hospital. In the evening he vomited up a pint of coffee-ground colored fluid, but whether this is due to hæmorrhage from the mucosa of the stomach (a characteristic of snake-bite, as has been pointed out) or otherwise, is conjectural. He made a good recovery.

Amœbic Dysentery.

IMPURE drinking-water is saddled with the burden of this difficult-to-cure disease, which DR. H. A. WEST declares is much more common than is generally supposed, and produces a very rapid anæmia and wasting which may however, be retarded, if not actually controlled, by a liberal diet and the exhibition of salines, and large doses of bismuth and caloi. The symptoms are very uniform in acute cases, being very similar to those of catarrhal dysentery; but they soon become chronic, being characterized by irregularity (alternating between improvement and relapse) in the nature and frequency of the stools with a tendency to alteration of different parts of the large bowel and a disposition to infiltration and undermining of the intestinal mucous membrane to afford a nidus for the destructive work of the amœbæ which multiply rapidly, and though easily killed by immersion in solutions of quinine, are not affected by injections of the same solution. Cleanliness with antiseptic enemata of argentic nitrate (15 grains to the pint) are of great value in destroying the micro-organisms and stimulating the intestinal ulcers to heal.

Catarrhus.

As the various catarrhal diseases though named by the portions of the body attacked, seldom or never occur singly, and being constitutional in nature possess the same general characters, though somewhat modified in local detail, according to the part affected, FORWATER thinks that all these catarrhal affections should be unified under the term

"*phagocytosis*" especially in: (1) The acute febrile and ultimate conditions suffered them all. (2) They were mutually contagious, and the contagion must be due to a germ, the pathogenesis of which had been found in all of them and after cultivation was capable of setting up conditions closely resembling those of them. (3) Though predisposition was here less important than in tubercle, still some individuals inherited a peculiar tendency to fall victims to this disease as they did to tubercle.

Phosphoric Acid in the Urine of Malarial Fever.

In chronic malarial cachexia the elimination of phosphoric acid does not seem to be affected, but REM-FLOOT and REMINGTON find that it considerably increases during the first 24 hours of malarial infection, and that, independent of the amount of food taken, or the increased quantity of urine voided, there is a notable diminution in the amount of phosphoric acid eliminated as soon as the temperature rises above the normal. This decrease is not proportional to the degree or duration of the fever, but if the fever be cut short by quinine or subside of itself, phosphaturia is usually observed, and this remarkable "unloading" of phosphoric acid continuing for several hours, pulls up for the retention noticed during the febrile paroxysm.

Merycism.

ONLY fifty cases have been reported of merycism, which DR. W. A. HAMMOND defines as "rumination and remastication in the human subject" always due to rapid eating and overloading the oesophagus. Though he quite agreed with other observers that a distinction should be made between congenital and acquired merycism, he did not admit its being a neurosis. He advocates no special line of treatment, and is uncertain whether crania operations can influence or lead to cure; but submits that he has obtained very good results from trephining.

SURGERY.

The Treatment of Pott's Disease of the Spine.

AS no operation can cut short this disease, and as recovery is postponed by unfavorable mechanical environment, DR. A. B. JUDSON thinks that we can best assist nature to promote arrest of destruction and the beginning of repair by putting the affected vertebrae in their best attitude by, as far as practicable, removing injurious pressure, by applying the most effective kind of retentive splint that will not only prevent the affected joint from moving, but will also relieve the bone of the duty of supporting weight and concussion. To do this effectively judicious antero-posterior pressure is required, but as in the corset and braces, the leverage necessary for the proper support is deficient, DR. JUDSON advocates the use of parallel steel uprights joined by a pelvic band and free at their upper ends which curve over the top of the shoulders and are kept in position by straps, which also exert a counter-pressure from before backwards to meet the pressure from behind forwards urged by the impinging of the steels on pads attached to the uprights at the level of the spinal projection and applied a short distance from the median line by each side.

The Bicycle as an etiological factor in lesions of the perineal region.

FABRIZIO TRENDRENO ROVERO and DE PEZZER contribute remarks on the evils personal to certain persons with tubular limbs wide apart. They are all agreed that bicycling produces hardness and rigidity of the perineum, labia, &c., causing pain, frequent urination and even a discharge per vaginam. The veins become varicose, producing hæmorrhoids, which pressure on the nerves produces numbness. In three instances

perineal abscess, uterine fibroids, and cysts, respectively, occurred. Then again the distressing hæmorrhoids and hæmipia produced by riding over uneven ground are a fruitful source of bladder irritability, cystitis, &c.

FABRIZIO recommends improved pneumatic saddles and insists on a more upright position while riding over rough and uneven roads, coupled with greater care and less speed.—*Practitioner.*

Abdominal Surgery on the Battle-field.

THAT laparotomy in dangerous internal hæmorrhage and visceral wounds of the abdomen is perfectly justifiable in military practice, is shown by SHAW, who suggests that permanent hæmostasis must be secured by ligatures or aseptic tamponade; but as soon as a man is wounded, he should be carried to the rear and temporary hæmostasis established by compression over the injured part and auto-transfusion by insular constriction at the base of one or more extremities while arterial bleeding may be arrested by digital pressure on the aorta below the diaphragm and venous or parenchymatous by sponge compression. Visceral wounds of liver or pancreas yield to suturing, aseptic tamponade or actual cautery, and those of the spleen or kidney sometimes require extirpation of the injured organ; but as with a very few exceptions, wounds of the stomach and intestines usually result in death if they are large enough to permit extravasation, they should be quickly and safely closed by a row of sero-muscular sutures, including a few fibres of the submucous and fibrous coats and the after-treatment directed to combat shock and prevent complications.

Ligature of Spermatic Cord in Hypertrophy of the Prostate Gland.

THE most rational way of treating prostatic hypertrophy, thinks EWING MEARS, is to obliterate sexual function and produce atrophy by castration; but as very few patients would consent to mutilation, ligature of the vas deferens was suggested as replacing castration and for gradually extinguishing the sexual function without disturbing the mental condition of the patient, as might be the case were the testes removed and terminating the horrible sufferings from the results of prostatic obstruction.

Operative Treatment of Wry Neck.

MIKULICZ advocates almost total removal of the contracted muscle, leaving only that part where it is traversed by the spinal accessory nerve, as he concludes that wry neck is a myositis fibrosa, the result of a chronic inflammation involving the whole of the sterno-mastoid, while the sterno-mastoid-hæmatoma sometimes seen in infants is due, not to effusion of blood, but to thickening and induration of the inflamed muscle.

Nephrectomy for Sarcoma of Kidney, in a Child twenty-five months old.

HAVING diagnosed malignant disease of the left kidney in a child of 25 months, DR. X. O. WENZEL performed nephrectomy, removing a fairly large rhabdomyo-sarcoma originating from the kidney. The child stood the operation wonderfully well, losing but little blood, and spontaneously urinating about two hours afterwards. She was dismissed from observation 15 days after the operation, and has since gained considerable flesh.

Incision of Pericardium for Pericarditis.

Pericarditis.

IN October 1893, a boy of 11 received a punctured wound in his cardiac region. This gave no pain and healed without medication; but after three months from diagnosis, cyanosis on both and cardiac failure, and at that time severe, Von Treussner punctured the pericardium with a fine

was removed, and a line of abscess laid, after which the wound was closed. A few days later, the patient was again taken up, and on tapping (4 times more) opened only tenacious solid, and there were symptoms of pleuro-pneumonia. It was resolved to open the pericardium freely, and after a litre of purulent fluid mixed with many large clots of fibrin were let out, the cavity was washed out with salicylic acid, and two drainage tubes inserted. Marked improvement taking place, the wound completely healed in 21 days.

OBSTETRICS AND GYNECOLOGY.

Urethro-Vaginal Abscesses.

THAT the usual symptoms show themselves, the patients seem usually in good health, although the pre-disposing causes may, as Dr. T. S. CULLUM points out, exist long before the physical manifestation in the urethro-vaginal septum of fluctuant tender tumours which varying from the size of a marble to that of a hen's egg, appear inside the vagina, but just behind the external orifice of the urethra. Oction may be painful, any sort of pressure will cause the tumor to discharge its contents through the urethra, as the sac-cavity can be entered by passing a catheter with its point downwards along the urethral floor. The treatment consists in carefully excising the sac and closing the opening with silk sutures, while among the possible causes of this condition are: congenital cysts, urethral diverticulum formed by a weak point in the urethral wall or by an arrested calculus, dilatation of SKENE'S tubules or of a lacuna of Morgagni, an abrasion of the mucous membrane creating a small pocket in which the decomposing urine sets up inflammatory processes or a suppurating cyst located in the urethro-vaginal septum bursting into the urethra. These sac-like dilatations in the urethral floor should not be confounded with cysts of GARTNER'S duct which being usually about the size of a pea, do not communicate with the urethra.

Treatment of Displacements by Pessary.

DR. DAVENPORT says:—

In cases of uncomplicated retroversion or retroflexion of the uterus the choice of treatment lies between shortening the round ligaments and the wearing of a pessary. A cure, either anatomical and symptomatic, or symptomatic alone, may be confidently expected from the use of a pessary in about 25 per cent. of all cases. Where a cure is effected, it is usually within a year or a year-and-a-half after the beginning of treatment. A large proportion of those not cured can wear a pessary without discomfort and do not wish an operation.

The operation for shortening the round ligaments should be limited to those cases where a pessary cannot be worn, to those who prefer it to wearing a support for years, to cases where vaginal treatment is inappropriate, and as supplementary to other operations.—*Amer. Jour. of Obstetrics.*

Menstruation in a Child.

G. E. BART showed at the Kiess Obstetrical and Gynaecological Society a girl, aged 6, who had commenced to menstruate regularly about twelve months previously. The catamenia recurred every three or four weeks, and lasted on each occasion from four to ten days. The breasts, external genitalia, and pubic hair growth resembled those of a girl 13 or 14 years old. The abdomen proved to be considerably enlarged, the circumference amounting to 35 centimetres. The examination revealed the presence of a fluctuating thick-walled ovarian cyst.—*B. M. J.*

A new method of producing premature labor.

Labour.

REYNOLDS gives a new method of producing premature labour, by means of an instrument which is described

as follows:—The instrument is composed of an introduction tube of some grammes weight, having the extremities flat, the end drawn out and shaped into a fine needle. This portion is intended to be introduced into the cervix. The introduction is curved and has a ring six centimetres from the end, which gives the measure of its introduction into the cervical canal. When this touches the os extensor, the tube is forced into the uterine cavity. In this conducting tube is placed a capillary tube with an ovoid ampulla at its extremity. This end very dilatible. To use the instrument, the entire tube is coated with vaseline and is placed inside the vulva passing a little beyond the flange-like end. The instrument is guided by the left hand into the vagina and the ampulla and into the cervical canal until the ring rests against the external os. The rubber tube is then injected, and as it fills, the ovoid end protrudes and gradually makes its way upward to the internal os. The metal tube is then withdrawn, the rubber balloon being left in place. He claims an infantile mortality of only 6 per cent. with absence of complications on the part of the mother. No change in fetal presentations has been observed.—*Amer. Jour. of Med. Sci.*

Abdominal Palpation of Obese Women.

DR. HARRIS SLOCUM has found a narrow zone on the abdominal walls where the fat in the muscular layer is deposited to a less extent than at other points. He describes this as a depressed curved line running from one anterior spine to the other, with its convexity toward the mœs venter. Along and near this line little fat is lodged. By depressing the finger tips the pelvic organs may be felt, the fat about the navel and below the zone being pushed out of the way by the pressure of the hand. In this way, he says, an effective palpation may be obtained even in the most obese. He has had satisfactory experience with it, personally, beyond that which had formerly been possible by palpation over the abdomen at large. The method cannot be carried out when there is much gaseous distension of the intestines, or when the dress is tight.—*Philadelphia Polyclinic.*

Extra-uterine Pregnancy; Elimination of the Fœtus per Rectum.

DR. SPANNOCHI reports the following case of extra-uterine pregnancy, remarkable for the mode of its termination. A robust woman, without a trace of disease of any kind, four months after a perfectly healthy labor, began to complain of pains in the hypogastrium. The symptoms pointed to an extra-uterine pregnancy, probably in the left Fallopian tube. A month later the sac ruptured, and the fœtus was discharged into the abdominal cavity. Reactive peritonitis around the foreign body came on; then followed suppuration and perforation of the intestine with discharge of pus. Owing to the continuous contractions caused by the presence of the foreign body, the intestine became dilated and prolapsed: finally, after twenty-eight days, the fœtus came away through the anus. After a considerable time complete recovery took place.—*Med. World.*

Cold Bathing during Menstruation.

Cold bathing during menstruation is a beneficial measure, provided women accustom themselves to the treatment by bathing every day for at least eight days before the arrival of the period, when they can continue during the menstrual flow without any danger. In the case of a very anæmic girl in whom this treatment was instituted, it gave most satisfactory results. However, before the recent Gynæcological Congress, held that cold salt-water baths facilitate the menstruation flow, the influence of genital life and thereby increase fecundity in remarkable manner.—*Dr. CURETTE in Gazette de Gynécologie.*

Correcting the Errors in Detained Placenta.

Out of 1,000 cases, representing 66 cases of correcting for retained placenta after abortion, all of whom recovered, points out that certain errors applied to the curette are not altogether rare, e.g., it has been termed "blind," "unstable" and "dangerous." This latter condition he considers to be especially true, as a careless operator may easily penetrate right through the uterine walls. These objections can, however, apply equally as well to any surgical instrument unskillfully handled. If the finger is used to explore the uterine cavity thoroughly, the curette is not a dangerous instrument. Such exploration, coupled with a fairly dilated cervix, are two conditions essential to ensure safety and efficiency in using the curette. Chloroform is unnecessary, a cutting, and not a blunt, curette should be used. Swabbing with creosoted glycerine, or iodoine, intra-uterine injections and plugging the vagina with iodoform gauze, constitute the *coup de grace* whenever the curette is employed.—*British Med. Journ.*

Should Antiseptic Vaginal Douching be made a routine practice during the Puerperium?

ANTISEPTIC vaginal douches have been more or less in vogue since 1848, but they were most popular between 1875 and 1885, and at one time it appeared that they would be universally adopted as routine prophylactic measures. FORDYCE BAKER (1854) was the first to use these injections in America, and in 1876 TARNIER recommended bichloride of mercury as an antiseptic intra-vaginal injection; but two years after, F. BAKER gave up the practice of vaginal douches. GALLARD THOMAS became its most enthusiastic champion, and in 1884 rushed the douching wave to its greatest height. Since then, however, it has gradually ebbed, and though opinion is much divided and some still answer "yes" to the question, "should antiseptic vaginal douching be made a routine practice in the puerperium?" DR. ADAM H. WRIGHT boldly replies with an emphatic "NO," because (1) it disturbs that perfect rest and quiet that are essential for a patient after labor; (2) the utero-vaginal canal being bruised, wounded and lacerated after labor, douching is unscientific on surgical grounds which demand rest, pressure, position and drainage, all of which are disturbed by vaginal injections and suppositories; (3) the normal vaginal mucus, which is strongly acid, restrains or destroys the pathogenic cocci. Vaginal antiseptic douches, instead of lessening the dangers accruing from the presence of bacteria in the vagina, may augment them by interfering with the normal acidity and thus chemically lessening the resistance of the tissues to pathogenic germs; (4) as supported by scores of instances, douching is actually dangerous. It disturbs clots, opening up avenues for infection, opens lacerations of the cervix and vagina, preventing them from healing, and has been known to cause septic endometritis by washing bacteria into the uterine cavity.

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.**Syphilis in Tuberculosis.**

QUIDORE insists that syphilis infection preparing a soil well-suited to the entrance and huge development of tubercle bacilli, especially predisposed to pulmonary tuberculosis. He finds also that, after the appearance of the tubercles for which it has prepared the way, syphilis either decreases in virulence or becomes latent.

The Calibre of the Human Intestine.

Based on his opinion on experiments made with M. CHAPT's anatomical balloon, and on previous measurements of the human intestine, M. CHAPT declares that the 17 millimetre button used in America is much too large for the shaft, not in general, and especially for the lower end of the shaft of the French subject, whose bowel is about equal to the 17 millimetre button. Now as French cooking is the best in the world, the question arises whether dainty dishes are a physiological mistake, and whether a partial arrest of development with a diminished calibre of intestine is a natural consequence of "making digestion" by means of elaborate cookery?

To preserve organised Sediments in the Urine.

BOHLAND lets the urine stand till the deposit fairly collects. When pouring off the supernatant liquid, he washes the deposit with saline solutions and transfers it to MULLER'S fluid (changing every 3 or 4 days) where it is kept for a fortnight, after which the MULLER'S fluid is carefully drained off and the hardening completed in absolute alcohol. By this means, and after staining with ERLICH'S neutrophil mixture, epithelium, leucocytes and casts were readily recognised; but SEVATOR complains that while plenty of mono-nucleated leucocytes were found in parenchymatous and interstitial nephritis, very few polynucleated cells were seen.

The Blood in Melancholia.

EXAMINATION of the blood of 12 melancholics demonstrated that in the acute or chronic stage of the malady the red blood cells were markedly diminished in number, and were at the same time curved; the haemoglobin was also reduced in like proportion. Although melancholia is not caused by blood-poverty, it is certainly associated with it, and a course of iron alone or with quinine and strychnine, as it improves the quality of the blood, produces also a coincident improvement of the melancholia, as well as of the general health.—*Omaha Clinic.*

Cause of Death and changes in the Organs after Scalding.

MARKUSFELD and STEINHAUS experimented on rabbits in order to ascertain and determine the cause of death from scalds. The ears of the rabbits were placed in water heated to a very high temperature, which caused their death whenever it rose to 56° to 66°C. The following changes occurred in the blood:—Globules were found, (separated globular processes from the red blood cells) also microcytes, poikilocytes, broken-down red cells and various thrombi in the veins and arteries of the kidneys, liver, lungs, cardiac muscle, brain and spinal cord. These thrombi were composed of blood plates which sometimes filled up the entire lumen of the vessel, and at others only a portion; the remainder containing red corpuscles and hyaline matter. During the experiments, the temperature of the rabbits rose considerably. The same changes occurred in the blood vessels by the pouring of very cold water over the animals.

The main vessels of the ears were also ligatured (it being impossible to ligature the ordinary arterial vessels, owing to capillary anastomosis). By doing so only a small amount of blood reaches the general circulation. The phenomena now observed were that in spite of the rise of temperature of the water (in which the ears were immersed) to 70° or 83°C, death did not ensue during the experiment. The blood changes appeared much later, and thrombi were very rarely seen. The authors conclude that, as a result of the great heat on the blood, chemical and morphological changes are produced

to it which give rise to "blood-plate thrombosis" in the brain and spinal cord (among other organs) which cause death.

Primitive Man.

CONSIDERING him from a geological point of view, primitive man appears very late in the history of the building of the crust of the earth, so late indeed, that the date of the human period must be referred to the rocks now in process of formation. One of the very few data at our command whereby we can locate primitive man beyond our present association is that coeval with him, many animals existed which are now extinct.

The form and size of the cranial development of ancient man, when compared with those occurring in certain species of our own race at the present day, afford a clue to the mental capabilities of the inhabitants of Europe in those early days. Some of these skulls found are smaller than those of the lowest savages of the present day, while others shew a much higher brain capacity.

It is strange that among the relics of the age immediately preceding the last great glacial period, no trace of man is found, and those who hold the developmental theory cannot possibly suppose that man was introduced on to the earth in that high stage of evolution in which we first find his remains. The search must be made considerably *earlier* if primeval man is to be discovered, *viz.*, in the more temperate strata, which were forming during the glacial period. Northern Europe being quite uninhabitable during this period. The ice and snow in many instances covered the highest mountains and overtopped them for 200 to 300 feet, filling up the North Sea entirely, and forming a vast ice connection between the British Isles, Scandinavia, Germany and France eastward, and stretching far out into the Atlantic westward. This state of things after lasting for thousands of years, gradually gave way under the sun's rays, until the genial, temperate climate, we now enjoy, supervened.—*Guillard's Med. Jour.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Albuminuria and Life Insurance.

THOUGH the presence of large amounts of albumin in the urine of a candidate for insurance calls for immediate rejection, still the *temporary* (*i.e.* occasional or intermittent) appearance of this substance *lessens*, if it does not remove, the presumption of renal disease as many *transitory* causes, such as lithæmia, oxaluria, over-generous flesh diet, exposure, &c., may produce temporary or transient albuminuria *without discoverable evidence* of organic disease, yet as behind the temporary exciting cause, there may be just a wee touch of cirrhosis or of Bright's disease in an incipient condition, which at that time shewing no appreciable symptoms, nevertheless pursues its murderous course to the bitter end. DR. J. N. DANWORTH points out that it is the duty of the examiner to the candidate as well as to the company he represents, to *patiently ascertain* the *actual* condition of the applicant, who may safely be insured if the albumen be present occasionally only and in barely perceptible quantity; but he must be rejected at once if *traces* of renal disease are found. The indications for rejection are: (a) cardio-vascular tension, (b) *occipital* headache with vertigo, (c) listless movements, tongue coated, lips pale, breath foul, and cadaverous or waxy look of the skin, (d) tube casts known also as hyaline casts, which are *invariably* present when a true organic lesion exists.

Nomenclature for the different classes of Infectious Diseases.

VAGUE terms and ambiguous quotations by medical men as to the precise nomenclature and proper differentiation of the classes of epidemic disease, being the most potent generator of vague fear, which is the mother of panic, Dr. W. H. THOMSON banishes the nightmare of misnomer and deadly diffusible gas that for generations past weighed upon the minds of medical men and laity, whenever epidemic diseases were thought of. He therefore concludes—rightly too—that a great many of these needless scares may be averted by the adoption of a *definite* nomenclature that, describing the various classes of infectious disease, not only indicates the specific micro-organisms associated with, or being the starting point of each of them, but also lays down the measures of disinfection applicable to their *certain* prevention. He divides infectious diseases into three classes:—(1) The *communicable*, whose origin is from an animal body, and which are again divided into the (a) *contagious* such as diphtheria, small-pox, measles, mumps, scarlet fever, &c., where simple proximity to the sick is sufficient to convey the infection to those susceptible to it, and isolation of the sick is essential to prevent infection; and (b) *non-contagious*, such as cholera, typhoid and tuberculosis, where isolation of the sick is neither needful nor effective, and where infection is not by simple proximity but through intermediate means of communication. (2). The *non-communicable*, whose origin is from a place or thing (marsh-land or protozoan, for instance) and *not* from an animal body. Such are ague, yellow fever and the generality of miasmatic affections. (3). The *septic*, such as hydrophobia, leprosy, erysipelas, syphilis, tetanus, &c., where infection has gained access by inflammation or a wound or damage otherwise to the skin or the mucous membrane.

Bicycling for Women.

THE above subject, from the stand point of the gynecologist, is touched upon in the *American Journal of Obstetrics* by DR. R. L. DICKINSON, who, after recounting the advantages but greater disadvantages of the gymnasium, dancing, riding and the sewing machine, gives to bicycle-riding the first place of importance as affording the best means of providing an all-round form of exercise. The effect on the circulation is the same as that of any *general* exercise, *plus* a specialized supply of blood to the leg muscles, and an increased rapidity of circulation in the pelvis, whereby the pelvic vessels, muscles, and in fact the whole pelvic floor are stimulated and rendered more active through the heightened tonicity. The author illustrates his article with frozen sections, one of which demonstrates the extreme varicosity of the valve-less pelvic veins, ensuing from strain during waist-constriction. From these he deduces the propriety of assuming an upright position in riding, and the setting aside of all stiff seats in the stays, &c. Eight cases are cited as having benefited from bicycle exercise, which must, of course, be graduated to the power of each individual.

Poisoning by Drugs.

BINZ speaks of poisoning by drugs administered by the rectum. He refers to cases of poisoning by corrosive sublimate, opium and chloral, morphine, chloral, carbolic acid, and atropine. The sublimate and carbolic acid were both used as vermifuges. In all the cases the dose of the agent employed was large. The medico-legal aspect of such cases is obvious. The vagina probably absorbs less readily than the rectum, yet cases of poisoning have also been recorded here. Recently it has been shown that potassium iodide, iodoforn, salicylic acid, salol, and antipyrin are absorbed from

the vagina, and then during pregnancy, the puerperium, and later, this power of absorption is increased. Agents administered per vagina or per os should, of course, be classed as internal remedies, and not as external ones. The same caution is used in injections into the bladder or uterus.

—B. M. J.

THERAPEUTICS AND PHARMACOLOGY. *Aseptic counter-irritation in the treatment of affections of the Urinary Organs.*

In obstinate cases, where subacute inflammation of the urinary organs has resisted most forms of treatment, MR. E. HENRY FENWICK, F.R.C.S., recommends incision over the viscous and free tearing down of the neighbouring cellular tissue with a carefully asepticised finger with drainage of the wound for a week as the most effectual mode of inducing cure and repair by exciting suppuration of a benign type in the cellular tissue of their immediate neighbourhood and by draining off the products of inflammation; but he cautions the surgeon to exercise extreme care and perfect asepsis during the operation, and to particularly guard against breaking into carcinomatous or tubercular deposits, and letting their contents leak into or spread over the area that has been laid open merely for drainage.

Creasote and the Tubercle Bacillus.

As the results of experiments from tuberculous sputum supplied by DR. ARNOLD CHAPLIN, and from close observations on the methods employed in treating consumptives with creasote, DR. W. KINGTON FYFFE concludes that though nothing can be done with an advanced case of phthisis, still if taken in the early stages, it is possible to prolong life, if not to cure, and here creasote steps in by stopping ventral fermentation, improving digestion and aiding in the assimilation of food and exerting a definitely restraining effect on the poison of phthisis. He notes however, (1) that when creasote is inhaled, the virulence of the disease is not affected. (2) When creasote was administered by mouth in doses ranging from 2 to 12 minims, three times a day, there was a diminution of the virulence, and this diminution became more extremely marked in proportion as the doses were increased. (3) Exposure to creasote fumes in a small sealed chamber of 700 to 800 cubic feet capacity probably gives similar results to the above but the cases operated on were too few to draw definite conclusions from. (4) Provided the disease had not gone too far, creasote injected under the skin had a markedly restraining effect on the tubercle bacilli, but there is danger of setting up cellulitis by the irritation of the creasote. (5) Repeated, but every time unsuccessful attempts were made to cultivate tubercle bacilli in serum from animals inoculated with tuberculous sputum obtained from patients using large doses of creasote, either by the mouth or by the creasote chamber.

Asefotida for Insomnia.

ASEFOTIDA is a valuable remedy in the insomnia occurring in the aged. A five-grain pill exhibited after supper and repeated at bed-time will often bring refreshing sleep. In mild delirium, and especially during the period of unrest that precedes an attack of delirium tremens, the injection, by the rectum, of two ounces of the mixture of asefotida will, in many cases, procure the much-needed sleep, without recourse to the more dangerous narcotics.—*Louisville Med. Monthly.*

Antiseptic Remedies in Skin Diseases.

ANTISEPTICS in the treatment of skin diseases differ in a great many respects from surgical antiseptics. A healing by

first intention, of most lesions is easily accomplished; certainly not if the corium has been destroyed; but even if it is only impaired, denuded of the epidermis, or if bullae have been formed, the process of separation may easily be accomplished by catarrhal (epithelial) suppuration, the product of which is the "dry scab" under which healing takes place easily and undisturbed. This is nature's own antiseptic routine, which we should try to imitate, as far as possible, by using remedies which, although inert as it were, are capable of absorbing moisture and forming a coating that furnishes protection against air and against infection from the outside. In this sense these remedies are better antiseptics than those which have earned their reputation in the realm of surgery as being destroyers or antagonists of micro-organisms.—DR. F. J. LISSEUR in *N. Y. Med. Rec.*

Treatment of High Arterial Pressure.

As in many cases of high arterial tension, the spasm of the vessels and the signs of cardiac exhaustion and dilatation are due more to hyper-excitability of the vasomotor system than to direct pathological change in the walls of the blood vessel, it is advisable to remove the pressure and give the heart rest and quiet by nervous sedatives which, if not direct cardiac depressants, certainly act as sedatives to this organ, and may be given with or without the use of nitro-glycerine, the use of which (latter) though indicated by the condition of arterial tension, is contra-indicated by reason of the headache which it produces in susceptible persons.

Turpentine in Hæmorrhage.

DR. SASSE states that he has obtained excellent results from the use of oil of turpentine in the treatment of certain kinds of hæmorrhage, and thinks it should be more frequently employed for this purpose than it actually is. In the incoercible hæmorrhage, for instance, which sometimes supervenes after the extraction of a tooth in a "bleeder," there is said to be no better treatment than plugging the socket with cotton steeped in oil of turpentine. DR. SASSE has seen one case in which this immediately stopped a very abundant hæmorrhage consequent upon the extraction of a tooth. After several other measures, including plugging with iodoform gauze, had failed to produce the desired effect.

In hæmorrhage from the mouth, in scorbutic patients, he has successfully had recourse to pencilling the gums every hour with pure rectified oil of turpentine; small doses of this remedy were also administered internally.

Lastly in a case of vesical hæmorrhage which had proved refractory to all other hæmostatic measures, the bleeding was completely arrested by the use of a mixture containing 1 per cent. of oil of turpentine, a tablespoonful of which was given every hour.—*American Druggist.*

HERRA recommends the following formula:—Aq. salicyl. 5-9; ichthyol. 10-9; glycerin. 30-9; spirit. menth. piparit. 30-0; spirit. lavandul. 30-0; spirit. vin. rectif. 60-0. Apply to the affected parts with a brush, several times a day.—*P. N. J.*

Correspondence.

MR. HART'S UTTERANCES ON INDIAN MEDICAL MATTERS.

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In his address on the last day of the Indian Medical Congress, DR. ERNEST HART said that "a second obstacle to the successful cultivation of medical research in India is the overloading of medical officers with clerical works of the most menial character, and which might be very well, and much more economically done by a less highly paid and less valuable officer." This remark of DR. HART's was not certainly meant for the medical officers in subordinate service, but to be true, it is more applicable to this latter class than to the members of the superior class, almost all of whom are provided with clerks, who, though not less highly paid than most of the subordinate medical officers, are certainly less valuable than they in the sense in which DR. HART applies the term civil medical subordinates in charge of sub-divisions, are at present nothing but so many jail clerks. As medical officers in charge of sub-divisions, they are and should naturally enough be considered as health officers of their respective sub-divisions, but Government does not avail itself, of their services in this way. The whole of their time is now being devoted to the executive works of sub-jails, which of late have become so numerous, as to require the hands of a separate clerk to perform their duties satisfactorily. A man with these and other executive duties to perform, can hardly be expected to do justice to his legitimate work. Strange to say the Inspector-General of Civil Hospitals, who objected to these officers being employed as Honorary Magistrates and Chairmen of Local Boards, &c., did not object to their being employed as clerks!

Medical subordinates in charge of sub-jails are called "Deputy Superintendents," a name by which one would understand that they are mere assistants of superintendents, while in reality they have to perform duties from those of superintendents down to those of a menial clerk and jailor, and consequently they are required to master the whole code of jail rules and regulations, and keep themselves acquainted with the voluminous circulars published every year. The sub-divisional officers who are styled "Superintendents of sub-jails," are only so in name, for their other duties leave them no time to look after the jail works, nor do they consider themselves responsible officers for the proper performance of these jail duties; neither does the Inspector-General of jails hold them as such. It is the Deputy Superintendents alone who are the sole responsible officers of sub-jails, though they could very well share their responsibilities with the Superintendents; for they cannot act independently, which mars the usefulness of this system of arrangement in not a slight degree. It is therefore necessary that the sub-jails should be managed by an officer entirely entrusted with the jail duties, even though there be honorary Superintendents; the sub-divisional officer exercising only a general control. The allowance now given to the Deputy Superintendents might be well spent in creating a new post for sub-jails styled "an assistant" or "sub jailor." Otherwise, as things

are at present, the energy and capacity of a professionally trained man of doing immense good to the public is thus lost and exhausted in preparing the jail returns and accounts, while he does his work with a grudging heart in the bargain. How glad would an Assistant Surgeon or a Civil Hospital Assistant be to devote even a fraction of his time (now spent in these clerical duties) to thinking over a surgical operation in order to perform it neatly and successfully, or to diagnose a case correctly? How much gladder would he be to try to ward off the visitation of an epidemic disease to his sub-division than pore over the Inspector-General of jails' *takud*, or to submit a correct manufacturing return! It is true that ill and under-paid as these medical subordinates are, most of them do not express their discontent for fear of losing their allowance, paltry though it be, nevertheless it is too true that every one of them bemoans his fate for being employed at a jail clerk for which he was never trained, nor intended. I do not know what saving Government effects by this arrangement of employing qualified men as clerks. I rather think they incur a great loss on the whole. This, it seems to me, is a penny wise and pound foolish policy. Are not Civil Assistant Surgeons prepared to work as Honorary Superintendents of sub-jails like sub-divisional officers if they have sufficient time at their disposal after performing their legitimate duties as medical officers? Cannot they take the whole responsibility of the management of a sub-jail in their own hands, if they are only freed from its clerical duties? I believe they can, and I venture to think that they would work *honorarily* with a cheerful spirit of independence.

Were a clerk or sub-jailor added to the jail establishments, from the allowance given to Deputy Superintendents, these officers, being thus freed from their clerical duties, could be employed by Government for inspecting the branch dispensaries of their respective sub-divisions, and it would do away, to a certain extent, with the necessity of maintaining a separate sanitary staff as proposed by the Indian Medical Congress. These officers in co-operation with the Local Boards and village unions can do any amount of sanitary work in addition to their other duties as medical officers in charge of sub-divisions.

Yours, &c., PURNA CHANDRA DASS GUPTA,
Assistant Surgeon, Kishoreganj.

KISHOREGANJ, 13th March 1895.

THE DANGERS OF PRIVATE PRACTICE.

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The Nattore extortion case has created great alarm in the mind of a certain medical man. I see, a poor doctor can be easily insulted and oppressed by any man, and at any time, especially if the former does not happen to be on good terms with the latter. This is so for two reasons, viz., (1) nature of the doctor's duty, and (2) his low social status. The insult being facilitated by the medical man attending his patient *alone*.

Had the social status of private medical practitioners been higher, such insults would, to a large extent, disappear. The highest fee of the best doctor in town seldom exceeds one gold mohur, while that of the best lawyer, usually exceeds ten gold mohurs. The highest

salary of a Deputy Magistrate is Rs. 800, but the most an Assistant Surgeon draws is Rs. 200 only! But two rupees are required to insult an Assistant Surgeon, who will not venture to go to court, both for want of evidence and want of funds.

Dr. GANGA GOVINDA SARKAR was most shamefully insulted and oppressed by MATHURA NATH PAL, whose conviction of six months' rigorous imprisonment was confirmed by the High Court. This is surely some consolation to Dr. GANGA GOVINDA SARKAR and to the general public. As regards RAJA JOGENDRA NATH ROY, their lordships were of opinion that there could be little moral doubt that he was privy to the transaction, but there was not sufficient legal evidence to shew that he aided and abetted it. I am really sorry for this want of legal evidence on Dr. SARKAR's side. For a poor man to secure sufficient legal evidence on which to convict a big zemindar, is not always possible or easy.

A doctor, who has ever had the misfortune of being a family attendant to a wicked zemindar, knows how fretful, whimsical, aristocratic and oppressive some of them are! They arrogate to themselves the rights and dues of veritable Kings and potentates, and are always styled "Rajas," and "Maharajas" by their subjects, who, while they cry out against the so-called oppression of the Government, are silent to and bear stoically (if not otherwise) the far greater oppression and usurpation of their own zemindars!

The Nattore case is not an isolated instance of a doctor's insult at the hands of a zemindar. I myself was once insulted with my family, by Babu RAM GOPAL ROY CHOWDHARI, the zemindar of Mohadeipur in Dinajpur. One night I was called to have a *tete a tete* with RAM GOPAL Babu, as was our usual custom, I being his family doctor; on that day, however, I declined the honor as I was indisposed. This omission on my part so much exasperated the zemindar, that on the following morning he himself with many of his *conferees*, came and occupied the house adjoining mine, purposely to insult me and my family. The respectable residents of the village took my side, and legal proceedings were instituted against RAM GOPAL Babu with the result that he was bound down by a bond of Rs. 1,000 and two securities of Rs. 500 each to keep the peace for one year. This was in April 1893. In 1894 he was again fined and bound down to keep the peace for another year! On account of his oppression, almost all the respectable residents of the village left the place, and I shall never forget those scenes of oppression by RAM GOPAL Babu, who decimated a whole village to a desert. I give below his own letter of apology, in order to convince the public that zemindars do insult doctors.

"MOHADEUPUR,

No. 555. The 31st January 1893.

TO BABU HARA KALI SEN,

Hospital Assistant, Mohadeipur Dispensary.

DEAR SIR,—I am sorry for all that passed between us here the other day, and I shall be glad if you would come back at once to your duty. We shall no doubt pull together on the same terms as we did before. The Magistrate and

Collector are here. I waited upon him (the latter) this morning and he gave me very sound instructions on all matters.

Yours sincerely,

(Sd.) RAM GOPAL ROY CHOWDHURI."

I trust the Indian Medical Association will endeavour to take some steps to put a stop to these insults to qualified private practitioners.

Yours &c., HARA KALI SEN.

RAIGA J, The 22nd February, 1895.

GOVERNMENT IGNORES THE CERTIFICATES OF PRIVATE PRACTITIONERS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The above subject demands the serious attention of the Government and of the Indian Medical Association. It is not for an individual or insignificant slight to myself that I now draw attention to it. It seems so unjust and preposterous that the certificates of private practitioners, who are persons of no less qualifications than the majority of those whose circumstances have compelled them to accept Government service, should be granted. This it appears to me is one of the main causes, why a certain class of qualified medical men (men who prefer to live by independent practices, and who, no doubt, consist of a large majority of the medical world), are daily growing insignificant in the eyes of the public. Certainly there exist but few men in a village who can afford to pay for the attendance of a qualified man regularly. And in the case of their being Government employees, they cannot produce the certificates of their *unofficial* medical attendants (however qualified they may be): and at times of emergency are compelled to secure the help of a Government medical man, whether they like him or not. Thus practically private practitioners are no longer held to be in the same rank with them. And when the Government does not trust or recognize these men, how can one expect the people at large to trust their lives in their hands? They, as private medical men are not even entitled to give a certificate at a simple police case, for a small bruise or hurt. I bring this before your kind notice, for lately a case happened in the Shillpore C. E. College. A student had an attack of simple fever and I gave him a certificate of ill-health; but Dr. DINDO BUNDOO DUTT of the said College refused to recognize any certificate, on the plea that I did not hold a Government appointment! I was compelled to bring this before the notice of the Civil Surgeon of Howrah, but he has not answered my letter yet! Will you be so kind as to inform me what the standing rule of Government is on this subject, and whether L. M. S's and M. B.'s are, or are not equally entitled to grant certificates?

Yours, &c., B. B. CHATTERJEE, M.B., Shillpore.

"WHAT ARE THE QUALIFICATIONS OF CIVIL HOSPITAL ASSISTANTS?"

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With reference to the article "What are the qualifications of Civil Hospital Assistants," by Dr. ALF. MCC. DALLAS, which appeared in your issue of 16th March

1895. I beg to append herewith (1) a statement of the subjects taught in the Madras Medical College for the Hospital Assistant Department, and (2) an extract from the order of the Government of Madras on the proceedings of the Director of Public Instruction, Madras.

(1) *Statements of subjects taught.*

| Subjects. | Nominal text books. | Actual works taught. |
|--------------------------|---------------------|-------------------------------------------------------------------------------------------|
| 1. Anatomy | Wilson's | (1) Latest edition of Gray's anatomy and (2) latest edition of Heath's practical anatomy. |
| 2. Materia Medica | Whitla's | (1) Mitchell Bruce and notes from British, and Indian Pharmacopœia's. |
| 3. Physiology | Ashby's | Notes from Kirke's. |
| 4. Medicine | Husband's | Notes from Robert's. |
| 5. Surgery | Walsham's | Notes from Treves's other works. |
| 6. Midwifery | Meadow's | Playfair's and notes from Galabin's. |
| 7. Hygiene | McNally's | King's manual and notes from Park's. |
| 8. Minor Surgery | Heath's | Do. |
| 9. Medical Jurisprudence | Husband's | Do. |

(2). *Extract.*

"The Director's suggestion that the Hospital Assistant Department should be thrown open to failed candidates for matriculation, need not be considered at present; there is no reason to anticipate an insufficiency in the number of matriculates in future years, and the only way of forcing the educational standard of Hospital Assistants is by adhering to the present admission rules until they are plainly proved to be unworkable." (Paragraph 1, G. O. No. 616, Educational, dated 18th August 1894).

Let me now ask whether DR. DALLAS is justified in passing such a sweeping remark on Civil Hospital Assistants in general? I respectfully request him to confine his remarks to vernacular licentiates of Bengal or Bombay, and not to extend them to those of Madras, who were also included in the generic term "Civil Hospital Assistants."

Yours, &c., V. S. A. P.

Madras Medical College.

MADRAS, 23rd March 1895.

REVIEWS.

THE MEDICAL ANNUAL FOR 1895. Demy 8vo. pages 640. (Published by JOHN WRIGHT & Co., Stone Bridge, Bristol.) Price 7s. 6d.

The Medical Annual for 1895, which has now reached its 13th year of publication, is no way behind its predecessors, indeed it seems to get better and better every year. There are no less than 35 contributors for this year's issue, and among the addenda may be mentioned the very excellent section devoted to *Eye-sight and School-life*, so ably contributed by SIMON SNELL, F.R.C.S. This article is embellished with 7 beautiful photo-tint plates. DR. G. E. SHUTTLEWORTH contributes an article on *Sporadic Crinism treated by thyroid extract*, which is also illustrated with plates. The anti-toxin treatment of diphtheria is

discussed by DR. ARMAND BRYSON in a very scholarly manner, and contains an epitome of his recent researches on the subject. We may mention that the list of contributors does not consist of any one special nationality or school. The authors belong to very diverse nations, and are scattered over many continents.

There are the usual lists of asylums, homes, hospitals and medical schools, hydrotherapeutic establishments, nursing institutions, tutors, &c., which combine together and enhance the general utility of the *Annual*. The plan and topographical arrangement of the work, as in former years, has been preserved. To the busy practitioner this volume should be especially dear, affording, as it does, the most valuable and up-to-date treatment and the most recent thought on matters medical. For its nominal price, the amount of information it contains, and the number of photo-tint and other plates explanatory of the sections devoted to them, the treatise to our reckoning stands *primus* among all others of this nature, while the excellent and superior quality of the paper, printing and binding are more than could be desired. MR. WRIGHT is to be congratulated for such an excellent issue as the one for 1895.

ANGLO-URDU MEDICAL HAND-BOOK OR HINDUSTANI GUIDE:

For the use of medical practitioners in India. Compiled by REV. GEORGE SMALL, M.A., Missionary to Asiatics in London and formerly Missionary at Benares; with the aid of SURGEON-GENERAL C. R. FRANCIS, M.D. (Lond.), M.R.C.P., L.S.A., &c., late of Calcutta Medical College, and of MRS. NASH, L.R.C.P., & S. late Medical Missionary, Hyderabad. (Calcutta: Thacker Spink & Co. p.p. 200.)

This little medical hand-book will no doubt be welcomed by medical missionaries and surgeons generally (male and female), who have completed their curriculum at home and contemplate coming out to India to practise. The author very properly recommends that the hand-book be perused concomitantly with their other studies, prior to leaving England, and also its adoption in the various hospitals, dispensaries and teaching schools in India as a sort of text-book for the training of nurses, and dressers, &c.

Certainly for those unacquainted with the vernacular (and even for the permanent Indian resident), this little *opusculum* is a boon. The various subjects treated of are divided into separate sections and grouped in alphabetical order for facility of reference. Surgeon-General C. R. FRANCIS adds a most valuable index to native medicines, accurately describing each drug and giving its therapeutic uses and dose. The index contains the *pharmacopœi* and vernacular terms used to designate the drug.

In addition to the discussion of matters purely medical, there are added *dialogues* (in English, with vernacular rendering) *between doctors and patients*, and a tabulated series of *helps to diagnosis*, which will, no doubt, be very helpful to the *dilettanti* student and the riper general practitioner, or medical missionary.

The work was originally intended for *lady* medical missionaries for the benefit of the down-trodden women of India, but we venture to think with the author, that it will be more generally useful.

Government Medical Gazette.

GOVERNMENT OF INDIA.

Surgn. Lieut.-Col. F. W. Wright, D.S.O., M.B., 6th Regt., Beng. (Light) Infy. furlough for one year.

Services of Brig.-Surgn. Lieut.-Col. G. Hutcheson, M.D., Surg. Commr. and Dep't. Genl. of Vaccination, N.W.P. and Oudh, replaced at disposal of Milly. Dept.

Surgn. Lieut.-Col. J. F. P. McConnell, M.D., F.R.C.P., I. M. S., Profr. Materia Medica and Clin. Med. Med. Coll., and ex-officio 2nd Physien. Coll. Hosp., special leave (s.p.a.) for six months.

Surgn. Lieut.-Col. R. L. Dutt, M.D., I. M. S., Civil Surgn., Hooghly, to offic. as Profr. of Materia Medica and Clin. Med. Med. Coll., and ex-officio 2nd Physien. Coll. Hosp., during absence of Surgn. Lieut.-Col. J. F. P. McConnell.

Surgn.-Col. L. D. Spencer, M.D., I. M. S., Beng. Estab., granted temp. rank of Surgn. Maj.-Genl. from 1st April, during absence of Surgn. Maj.-Genl. R. Harvey, M.D.

Brig.-Surgn. Lieut.-Col. G. Hutcheson, M.D., I. M. S., Beng. Estab., granted temp. rank of Surgn.-Col. from 1st April, during absence of Surgn.-Col. G. Thomson.

Brig.-Surgn. Lieut.-Col. G. McBride Davis, M.D., I. M. S., Beng. Estab., granted temp. rank of Surgn.-Col. from 31st March, vice Surgn.-Col. L. D. Spencer.

Surgn.-Col. R. Harvey, M.D., D.S.O. and C. E. McVittie to be Surgn. Maj.-Genl., 1st April.

Surgn.-Majs. George Spiers Alexander Ranking, M.D., Robert Davidson Murray, M.B., Dennis Wood Comins, Patrick Fenelon O'Connor, James Moran, M.D., William Allagon Simmonds, Roderick Macrae, M.B., Thomas Elwood Lindsey Bate, Nibtram Borah, M.B., who have completed 20 years' full pay service, to be Surgn. Lieut.-Col.

Surgn.-Col. Jesse Griggs Pilcher, I. M. S., to retire from 29th March.

Surgn. Lieut.-Col. Thomas Robinson, M.B., to retire from 30th March.

BENGAL GOVERNMENT.

Syed Ali Hussin made over charge, Muzaffarpur Jail, to Surgn.-Maj. A. Tomes on 28th March.

Surgn.-Maj. F. S. Peck made over charge, Muzaffarpur Jail to Syed Ali Hussin on 24th March.

Surgn.-Capt. E. Harold Brown made over Darbhanga Jail to Asst. Surgn. Nobin Chunder Dutt on 26th March.

Asst. Surgn. Benode Behary Ghosal to do superny. duty at Presdy. Genl. Hosp., until further orders.

Asst. Surgn. Abinash Chunder Ghosh, Teacher of Med. Path. Hyg. Cuttack Med. School, leave for two months and a-half.

Asst. Surgn. Saroda Prosad Das apptd. to sub-divn. and dep'ty., Brahmanberia, in Tippera Dist.

Services of 1st class Milly. Asst. Surgn. P. Toomey, Dep't. Supdt., Dalanda Lunatic Asylum, placed at disposal of Govt. of Punjab.

First class Milly. Asst. Surgn. J. R. Rodricks, Med. Offr., to be Asst. Dep't. Supdt., Dalanda Lunatic Asylum.

First class Milly. Asst. Surgn. V. M. Carleton apptd. med. offr., Sandheads.

Asst. Surgn. Nobin Chunder Dutt made over Darbhanga Jail to Surgn.-Capt. F. P. Maynard on 27th March.

Surgn.-Maj. G. Jameson made over Malda Intermediate Jail to Babu Ram Narain Banerjee on 1st April.

Surgn.-Capt. J. G. Jordan made over Barisal Jail to Surgn. Lieut.-Col. Keshi Pathy Gupta on 2nd April.

Babu Devo Nath Dey made over Jalpaiguri Jail to Dr. J. L. Headley on 2nd April.

Babu Ram Narain Banerjee made over Malda Jail to Asst. Surgn. Narendra Nath Gupta on 8th April.

Surgn.-Capt. B. H. Desre as Civil Surgn., Howrah, 1st to 9th April, during absence, on furlough, of Brig.-Surgn. Lieut.-Col. H. Farves.

Surgn.-Maj. R. D. Murray, Offg. Civil Surgn., Chittagong, apptd. Civil Surgn., Howrah, until further orders from 10th April.

Services of Surgn.-Capt. R. E. Deane placed at disposal of Govt. of India in Milly. Dept.

Surgn.-Capt. J. R. Ains granted six months' extra ordinary leave (s.p.a.) without pay in extension of furlough associated, 30th Oct. 1904.

First class Milly. Asst. Surgn.-Capt. Charles Apple, Asst. Surgn. Supdt., Family Genl. Hosp.

Surgn.-Capt. F. P. Maynard made over Darbhanga Jail to Asst. Surgn. Nobin Chunder Dutt on 26th April.

Asst. Surgn. Mohanrao Nath Gupta, Sandheads, Sandheads Medica, Campbell Med. School, leave for two months.

Asst. Surgn. Ganes Chandra Mishra to do superny. duty at Med. Coll. Hosp., 6th April.

Asst. Surgn. Baroda Kanto Roy to do superny. duty at Med. Coll. Hosp. from 18th April.

Surgn. Lieut.-Col. J. F. P. McConnell, M.D., F.R.C.P., I. M. S., Profr. Mat. Medica and Clin. Med. Med. Coll., and ex-officio 2nd Physien. Coll. Hosp., special leave (s.p.a.) for six months, from date on which he may avail himself.

Surgn. Lieut.-Col. B. L. Dutt, M.D., I. M. S., Civil Surgn., Hooghly, to offic. as Profr. of Mat. Medica and Clin. Med. Med. Coll., and ex-officio 2nd Physien. Coll. Hosp., during absence of Surgn. Lieut.-Col. J. F. P. McConnell.

Surgn.-Maj. Robert Davidson Murray, M.B., Dennis Wood Deane Comins, Roderick Macrae, M.B., who have completed 20 years' full pay service to be Surgn. Lieut.-Cols, 31st March.

Surgn.-Capt. Granville Jameson, M.B., who has completed 12 years' full pay service to be Surgn.-Maj., 31st March.

PUNJAB GOVERNMENT.

Surgn.-Capt. W. H. E. Woodwright, charge of Jhelum on 22nd March.

Transfers.—First class Hosp. Asst. Sawan Mal, from Amritsar to Phillour Diap., Jullundur Dist., which he joined on 14th March, relieving 1st class Hosp. Asst. Barkat Ali.

First class Hosp. Asst. Barkat Ali, from Phillour Diap., Jullundur Dist., to Lelah Diap., Dera Ismail Khan Dist., which he joined on the 23rd March, relieving Asst. Surgn. Lachman Das, I.

Asst. Surgn. Lachman Das, I, from Lelah Diap., Dera Ismail Khan Dist., to Delhi for genl. duty, 26th March.

Milly. Asst. Surgn. J. T. Weston is apptd. to offic. temp. as Supdt. of Chenawan Central Jail, from 26th March, vice Surgn.-Capt. D. T. Lane.

Surgn.-Capt. G. H. Frost assumed charge Dera Ismail Khan Dist., on 31st March, relieving Surgn.-Maj. G. S. Griffith.

Milly. Asst. Surgn. J. T. Weston reported himself at Lahore for duty, 16th March and assumed charge of Muzaffargarh Dist. 23rd March, relieving Asst. Surgn. Jaswant Bai, Rai Bahadur.

Asst. Surgn. Jaswant Bai, Rai Bahadur, resumed charge of Muzaffargarh on 25th March, relieving Milly. Asst. Surgn. J. T. Weston, transferred.

Asst. Surgn. Fattah Chand, M.B., is apptd. to offic. as Civil Surgn., Rohtak, from 27th March, vice Surgn.-Capt. C. H. James.

Services of Surgn.-Capt. C. H. James, offg. Civil Surgn. Rohtak, replaced at disposal of Govt. of India in Home Department from 27th March.

On return from priv. leave, 1st class Hosp. Asst. Sadi Khan resumed charge of Shahkot Diap., Gujranwala Dist., on 30th March relieving 3rd class Hosp. Asst. Fazl Elahi.

On return from priv. leave 3rd class Hosp. Asst. Alam Shah was apptd. to Jhelum Jail and Police House, which he joined on 25th March, relieving 1st class Hosp. Asst. Parmanand.

Transfers.—Asst. Surgn. Gobind Ram, doing genl. duty at Meoltan, to Ry. Hosp., Khanpur, N.W. Ry., which he joined on 8th March, relieving Asst. Surgn. Jai Kishan Das.

Asst. Surgn. Jai Kishan Das, from Ry. Hosp., Khanpur, N.W. Ry., to Kulu Diap., which he joined on 26th March, relieving Asst. Surgn. Ram Narain, II.

Asst. Surgn. Alla Ditta, from Rawari Diap., Gurguon Dist., to Umballa Civil Hosp., which he joined on 25th March, relieving Asst. Surgn. Khazan Chand.

Asst. Surgn. Bani Narain, I, Asst. to Civil Surgn. at Delhi, relieved Asst. Surgn. Hool Chand of Delhi Civil Hosp. on 26th March as temp. measure.

Services of Asst. Surgn. Hattam Das, Imperial Lab. being no longer reqd. by Fisheries Dept. he reported himself to Principal, Lahore Med. Coll. on 23rd March for genl. duty at Mayo Hosp.

Asst. Surgn. Mangal Singh, Mayo Hosp., Rawalpindi Dist., has been placed temporarily on leave from 18th March. 2nd class Hosp. Asst. Goverdhan Das, from Bawalpur to Rawalpindi Dist., which he joined on 18th March.

Hosp. Asst. Mangal Singh, Imperial Dist., from Mayo Hosp., Lahore, to Mayo Hosp., Rawalpindi Dist., which he joined on 1st April, relieving 3rd class Hosp. Asst. Goverdhan Das, who reverted to Rawalpindi Civil Hosp. on 2nd April. Asst. Surgn. Khanna Chand, from Simla to Sialkot Civil Hosp., which he joined on 28th March, relieving Asst. Surgn. Mehta Duni Chand.

Second class Hosp. Asst. Mangal Sain, from Anandpore Disp. to Hoshiarpur for genl. duty, from 18th March.

The services of 3rd class Hosp. Asst. Sant Singh and 3rd class Hosp. Asst. Mangal Sain, doing genl. duty at Hoshiarpur, were placed at disposal of the N.W. Ry. for duty in connection with pilgrim traffic, respectively, from 22nd and 30th March.

S. K. Mehta.—Apply to the Surgeon-General with the Government of Bombay, stating your case in full.

P. G. (Calcutta).—There are two Eurasians in the Calcutta Medical College; one a professor and the other a resident.

Hospital Soup.

T. M. WILKES. In answer to "Hospital Surgeon" in the *English Medical Journal*, about soup, I can commend both for cheapness and nutritive quality, the following recipe. To 1 lb. of lentils add 10 breakfast-cups of water, 1 onion, small pieces of carrot and turnip, pepper, and salt, and a lump of butter, fresh dripping, or ham bone, Boil two hours and a half and strain.

BIRTH AND REGENERATION OF THE HEART AND KIDNEYS.

DR. BOLLINGER, director of the Anatomico-pathological Institute in Munich, asserts that it is impossible to find a normal heart and normal kidneys in an adult resident of that city. The reason for the change shown in the two parts upon these organs is the drinking of impure Munich beer, and the resulting impurities and regeneration are described in his paper. A second and third generation of the city was observed in the same manner, but the third generation was not observed in the same manner, as that the third generation was not observed in the same manner.

OBSERVATIONS ON PARALYSIS AGITANS.

By SURGEON-CAPTAIN PATRICK HENRI, M.D.,

F.R.S.E., F.R.C.S.E., D.P.R., (Cantab).

Lecturer on Medicine, Hyderabad Medical School.

THE rarity with which one meets with cases of *paralysis agitans* (PARKINSON'S paralysis) in India, makes it perhaps interesting to note the circumstances under which each case occurs. The following are the notes connected with the third case of the kind I have met with in India: the first being one under the care of the late Surgeon-General D. B. SMITH in the Calcutta Medical College Hospital in 1879; the second being that of a lascar on board of a merchant sailing vessel known as the *John Davis*, in 1884.

Bhaji Rao, Hindoo, *æt.* 40 years, with 21 years' service as a pioneer in His Highness the Nizam's Regular Troops, came under observation on the 25th October 1893, having been transferred from one of the district stations of the Hyderabad Dominions for treatment in the Staff Hospital in Hyderabad. His native place was Gya, near Patna. He stated that two years ago, he began to notice that he was unable to march with his company with the same facility that he could before, that his speech was somewhat interfered with, that his head trembled as soon as he attempted to do any manual work, and that his body shook all over when he stood erect.

The previous history of the patient, as far as we are etiologically concerned, is, that he worked as a pioneer, and as such, was chiefly engaged in such occupations as road-making, excavating soil for various purposes, and especially for the construction of buildings. The work was sometimes severe; but, as a rule, did not exceed five hours a day. He had often been drenched on the roads, and otherwise exposed to inclement weather. Like all our local pioneers, he had suffered severely from the results of malarial infection, and, four years ago, had been on six months' furlough, after several attacks of ague, resulting in incipient malarial cachexia. There was no history of syphilis, nor of alcoholism. Careful inquiry was made as to any previous injury with negative results.

The patient first noticed, amongst the early symptoms, that he could not use either spade or pickaxe with the dexterity and freedom that he could normally, and that these implements of his calling, occasionally fell out of his hands whilst using them, and next, that when on parade, he would be in a state of terror and anxiety the whole time, lest his condition should be noticed. He also observed that the left side was more affected than the right, but from the beginning, all the muscles in the body were more or less implicated.

Present condition.—On admission into the Staff Hospital, it was found that the patient was suffering from an advanced stage of the disease. He was considerably emaciated, and much debilitated. Bowels constipated. The most pronounced symptom was that of tremor, which, on the patient's standing, was visible in every group of muscles of the body, and in all groups the vibrations were rhythmic and synchronous. The only muscles which appeared to escape were those of the head, face and trunk, although

the muscles which proceeded from the latter partook in the general tremor when the patient was excited, fatigued from long standing, or when under observation. Further, under these circumstances, the length of the oscillations became greater and greater, until eventually they threw the patient out of his equilibrium, and he was obliged to sit down. The number of vibrations remained 135 per minute under all circumstances, varying only to the extent of 5 or 6 oscillations above or below that rate.

The tremors of the muscles of the neck and arms, were such as to move the neck backwards and forwards, much the same as in senile tremor, whilst that of the legs was lateral.

The muscles of the larynx were also affected, and gave the patient's voice a peculiar, but uncertain, high pitch. He would begin talking fairly naturally, although always very deliberately, and in a curious manner, cutting words short, or not uttering the end of the word at all; but as he went on speaking, the voice would become "shaky," one word or syllable being uttered in a bass, and the next in a treble key. "There was no tremor of the labial muscles, no difficulty of deglutition, nor nystagmus. Symptoms of serious implication of the spinal cord now developed; for he began suffering from a complexity of clinical manifestations, which appeared to shew that the anterior and posterior grey cornua, and the white matter of the lateral and postero-external columns were condensed, so that he had certain symptoms of adult spinal paralysis (polio-myelitis anterior subacuta), loco-motor ataxia, and LANDRY'S paralysis, besides which, the early signs of lateral sclerosis were fairly pronounced. Patellar tendon reflex, was exaggerated and ankle clonus was present. Rigidity of the muscles alternating with relaxation, was likewise a marked feature. The muscles had undergone considerable diminution in volume, especially those of the legs, the "reaction of degeneration" was present, although by no means so marked as we get it in true essential paralysis, or adult spinal paralysis.

Muscular weakness was marked, and progressive. When lying on his back, all vibrations ceased, but when asked to perform some act which brought certain groups of muscles into action, those groups would vibrate as they would if he had been standing. The electrical reactions of the unaffected muscles were normal. Later on, there was decided increase of the patellar tendon reflex on the left side, and the ankle clonus continued markedly increased, but there was no apparent exaggeration of the superficial reflexes.

The true festinating character of the gait was developed in its entirety, but there is no doubt but that the centre of gravity of the body was displaced, the symptom of retropulsion, or the mode of progressing backwards and threatening to tumble "head over heels" was present. These two symptoms were not manifest however, until the patient was either pushed forwards or backwards, or told to proceed rapidly in either direction. The speech was slow and deliberate. He could not follow a long sentence or question, nor give answers requiring more than three or four words.

The history of the case shews that the slowness of speech did not appear for fully 12 months after the tremor began.

The patient was kept under observation and treatment for a period of four months, during which time his whole condition retrogressed, muscular weakness becoming very evident. By this time it appeared that a partial sclerosis of the whole transverse section of the cord had developed.

Tremor was now much less marked, except when performing some action, but it was present (even) when lying down, ceasing only during sleep. The gait altered somewhat to that of the ataxic character, and the patient could not maintain his equilibrium when placed in the ataxic position, nor walk along a straight line without threatening to fall. In standing, his body bends at an angle of about 30 degrees, the head, shoulders and trunk participating in forming the curved angle. The natural result of this is, that when he attempts to move forwards, the angle is increased, the shoulders are rounded, and the patient looks on the ground as in ataxic progression—the centre of gravity being displaced. When told to walk forwards, he does so with his eyes fixed on the ground in a slow, deliberate way, as if he had to rivet his whole attention upon his progression, and not in a hurried shuffle of the feet, as was the case a few minutes ago. Paresthesia in the form of delayed sensation, acinesia, &c., were now marked.

At this time the speech was slow and drawing. The mental faculties enfeebled, his intelligence being limited to answering the simplest questions, and these only after they were repeated several times. There was no difficulty of hearing nor apparent change in vision, nor were there any ophthalmoscopic pathological signs. ARGYLL-ROBERTSON pupil was absent, nor had there been rheumatism or other pains of the limbs. As already remarked, there was no nystagmus, nor was there any conjugate deviation of the eyes, nor vertigo, which are so common in insular sclerosis. There was well-marked *annulus annulus* with rigid and somewhat tortuous arteries. There were no indications of heart disease of any kind. The face was expressionless. He would remain in bed for several consecutive days without saying a word to any one, not even to the sepoy who was placed over him as sick orderly. He was in no way emotional; could swallow liquids and solids well, and there was no trickling of saliva from the mouth. There was no apparent cause, for the disease no sudden shock, no history of alcoholism, syphilis, &c., except exposure, which developed intense malarial infection.

The man's age is against senile paralysis, and besides it did not begin in the head, nor is the head more affected than the rest of the body.

It is in no way like post-hemiplegic tremor, or post-hemiplegic chorea, which is confined to one side with a history of preceding hemiplegia.

All forms of treatment were tried without avail. Sedatives and nerve-tonics proved useless. He was in hospital for 12 months under a good and liberal diet, cod liver oil, &c., yet no change ensued.

Considering that the case was one of malarial infection, we administered arsenic and quinine systematically for three months, in large doses. At one time he was getting as much as 10 minims of Fowler's solution and 10 grains of quinine three times a day, but without the slightest effect on the

progress of the disease. He likewise got 15 grains of iodide of potassium three times a day, for a month, without any change in the symptoms. It was at first thought that the case was one of disseminated sclerosis, but the tremors are constant and the oscillations very rapid and small, instead of being large or passing through extensive waves; further, the tremors partly ceased or at least lessened during voluntary movements, thus differing from insular sclerosis, in which they are most marked. There is no nystagmus nor is the speech of the "scanning" character.

The slowness of speech and movements, which latterly became well developed, are like those of myxedema, but the main symptoms of that disease are absent; the tremors are regular repetitions of the same movements, the amplitude of each tremor being very limited.

There was a general wasting of the muscles in proportion to the progressive debility of patient.

The disease began in his hands, forearms and arms; it then affected the head. The fingers shewing the usual movements as of 'rolling a pill'. He constantly complained of an "internal heat" and would keep no clothes on.

The patient was profoundly depressed and melancholic, and is said never to have smiled since admission into hospital. He is still very intelligent, sleeps well, except if awakened during the night after which, he finds that he cannot get back to sleep.

There is no difficulty in eating or swallowing. With such highly complicated clinical phenomena, the localization of the seats of the lesions present can scarcely be made with any pretence to accuracy. I would hazard the opinion, however, that this is an instance of the mixed lesions we sometimes come across in chronic cases of malarial infection, arising from partial sclerosis of the whole transverse section of the cord, and partly from a modification in the blood-supply due to the blocking up of the blood-vessels by embolic of pigment, disintegrated malarial plasmodia.

The presence of numerous foreign particles in the blood-vessels may set up a round-celled proliferation and hyperplasia, whilst the partial removal of the blood-supply due to emboli, gives rise to atrophy of the nervous structures involved.

Similar changes may also have gone on in the brain, for a lesion of the cord alone could scarcely be responsible for all the symptoms. It is at once clear that the symptoms correspond with no single disease yet described, but run into, and overlap several maladies due to the implication of different regions of the cord.

HYGIENE IN INDIAN SCHOOLS.

By JOHN MORTON, M.D.

Mussoorie.

A CLEAN school is a model school, and delights the hearts of parents when they come to visit their children or put them to their studies for the first time. It may be said that no greater recommendation can be given to a school than to say it is perfectly clean. And yet in India, where servants are numerous and labor cheap, what little attention is paid to cleanliness! In this term I include every form of sanitation. A good clean school is an index to its tone. One can always tell, judging by this criterion, what

the washing and maimers will be. Whether the masters are gentlemen or otherwise. For it is one of the traits of a modern gentleman to have his person and environments fastidiously clean. To such a one a dusty desk or an improperly tilted black-board, should be as repellent as the sight of a leper. Parents complain a great deal about the uncleanness of schools, but they should not only complain, they should insist on cleanliness in every detail of management. What is it that marks the English public schoolboy as a gentleman wherever he might roam? I unhesitatingly say it is cleanliness. Cleanliness in person, cleanliness in the class-room, in the lavatory, in the latrine, in the dormitory, in food and drink and in clothing, and it will follow in thought, in education, and in the future career of every boy. With this prelude I would draw attention briefly, to a few points which head masters and mistresses should always bear in mind, and be ever ready to carry out without even a suggestion from the medical attendant.

Let us take into consideration first the *ventilation* of a School. Every day a certain amount of fresh air is necessary for the health of its—generally speaking—crowded pupils. The dormitory windows should be opened out immediately the boys or girls leave it, and kept open till an hour or so before sunset. The bedding ought then to be aired by sun light, if there is any during the day, otherwise by being thrown over wire ropes hung in the middle of the rooms. *Rezas* or quilts are an abomination, and no parents should ever be asked to supply them to the boys. Blankets can be washed and aired, and are the only suitable covering in a school. Iron-beds are a *sine qua non*, and *newar* ones are an insanitary sin. White-washing the whole of the buildings at least once a year, is absolutely demanded by the laws of health. Over-crowding will cause boys to be thin and weakly, and will deteriorate the *physique*, and ought on no account to be tolerated. The pillow-cases and bed-sheets require washing once a week, and should never be overlooked in the *dhobies'* list. Leaving the dormitory, let us now walk into the bath-room. It delights the heart of the doctor and the intelligent parent to see it well swept, with a washing-bowl or basin for each boy, clean and laid out in order, and separate towels for each boy hung over another wire rope to dry. Carbolic soap (CALVERT'S) should be in the possession of each pupil. A hot-water apparatus in hill schools should always be kept ready, so that each pupil may have a bath at least twice a week, if not oftener.

The *drainage* of the school is another important matter. Every drain requires daily inspection to prevent its clogging or retaining water of any kind.

The *refectory* should be absolutely without sauce. Dining tables should, once a week, be scrubbed down with sand and hot water, so that bread-crumbs may not enter into the crevices (the natural procreation of Indian-made tables), and decay.

Latrines require tarring frequently, and the disposal of excreta should receive the most careful attention. Separate vessels must be provided for urination. Each boy or girl should pour a scoopful of sand into the vessels after defecation. The filter for drinking water requires to be closed, and each boy should possess a separate

drinking-glass to receive water from the tap. The present system of a tinpot attached to a chain, is a relic of the insanitary age, and should be abolished at once. The food demands a separate man's attention altogether. He is to see that meat and vegetables are fresh, and that the meat is well-nourished and free from disease. The bread requires care in preparation, and the contractor's bakeries ought to be inspected, and the processes of kneading and baking carefully observed. Any filthiness ought at once to be checked. Fruit is necessary for a healthy diet, and should be well washed before being served.

The *Volunteer movement* has done much to inculcate habits of personal cleanliness and care, though it has a few drawbacks. The military exercises train the mind to precision, and the attire to uniformity, but, volunteer camps cause unnecessary fatigue and illness, and head-masters ought certainly to fight against the boys being dragged out for miles and days for these manoeuvres. Each master, before beginning lessons, should inspect the nails and hair of each boy and give marks and prizes to the most sanitary boy at the end of the year. In some schools it is customary to have one comb and hair brush only. This practice is highly reprehensible, and should not be countenanced for a moment. Hair brush factories are numerous and cheap now, and each boy should be the owner of his own brush and comb.

(To be continued).

CREMATION AND BURIAL*

By P. R. HAY JAGANNADHAM, B.A., M.B., C.M., (Edin.)

Khulna.

It is indeed matter for congratulation with the scientific watchman of the signs of the times, in his advocacy on the side of the Torch in the battle between the Torch and the Spade of to-day, to note the fact that the number is increasing and steadily increasing of those "who hail with satisfaction and joy, the prospect that a chariot of fire may receive them and not the cold and darksome grave."

Properly to appreciate the benefits that would result from the adoption of the system of Cremation, it is necessary briefly, to consider the evils for which the system of Inhumation is answerable.

The buried dead have poisoned and still poison the living:—Dr. PARKES of Netley says: "Burying in the ground appears certainly the most insanitary of the three methods—by land: by sea: by fire. The air over cemeteries is constantly contaminated, and water—which may be used for drinking—is often highly impure. Hence in the vicinity of graveyards, two dangers to the population arise; and in addition from time to time the disturbance of an old graveyard has given rise to disease. It is a matter of notoriety that the vicinity of graveyards is unhealthy."

The placing of a dead body in a grave and covering it with a few feet of earth does not prevent the gases generated by decomposition, together with putrescent matters which they hold in suspension from permeating the sur-

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

resisting soil still seeping into the air above and the water beneath, with enormous force is exercised by the gases of decomposition. The layer of earth above the bodies is insufficient to absorb the putrid gases evolved. In 1949 it was calculated that for "the 52,000 annual interments in the City of London, no less than 2,572,800 cubic feet of gas is evolved," the whole of which, beyond what is absorbed by the soil, must pass into the water below, or the atmosphere above.

The vitiation of the atmosphere in the vicinity of graveyards lowers the vital powers, gives rise to low fevers, produces faintness and nausea, headache, diarrhoea, ulcerated sorethroat, disease of the lungs, frightful malignant disease of the throat, dysentery, depression and functional disorders of the nervous system, and malignant fevers. The long duration and frequent fatality of disease in the vicinity of graveyards is well-known. Those living near graveyards "forfeit one-third of the natural duration of life and working activity." PATTENKOFER has found that carbonic acid gas is a pulse-lowering gas. Persons walking past a burying-ground have been taken ill; while grave-diggers have died in entering a grave.

The using of water contaminated by subsoil and subterranean graveyard infiltration, has given rise to low fevers, dysentery, fearful epidemics, cholera and typhus. Such water often possesses a strong odour, marked color and taste, and is found to be loaded with organic matter.

The re-appearance of the plague at Modena, due to excavations made in ground, where three hundred years previously, the victims of the plague had been interred—An immediate outbreak of the disease at Eym in Derbyshire, caused by the digging up of the plague burial-grounds—Enhancement in virulence of the cholera which visited London in 1854, caused by the excavations made for sewers in the site where the victims of the plague of 1665 were buried—The prevalence of the fever in Rome, declared by PLAYFAIR to be due to exhalations from the soil which is saturated with organic matter—The decimation of a town due to the soil of a burial-ground being deposited for manure in many of the gardens in the neighbourhood of the parish church of Minchinhampton—The outbreak of a plague in Egypt traced to the opening of a disused burial-ground near Cairo—The immediate outbreak of small-pox among the workmen who opened a small-pox burial ground one hundred and fifty years old—The outbreak of typhoid fever at a vicarage in Bournemouth—Blood-poisoning in the vicarage of a Hampshire county village—The history of the Aldgate Pump—The breaking out, according to Dr. McEWAN, of pyæmia in the new surgical hospital at Glasgow, which was built over the old burying-ground for cholera patients—St. Margaret's burial-ground near the Houses of Parliament—The Pere-la-Chaise, Montmartre and Montparnasse—A building used as a barrack near a Liverpool Churchyard—The Cimetiere de la Trinite—St. Botolph's Churchyard, Aldgate—Wells near a churchyard at Leicester—Wells below the churchyard of St. Louis in Versailles—Wells of the Place Gambetta below the monumental cemetery of Milan—Water-poisoning due to infiltration from the cemeteries of the hamlets of Rotondella and Bolette—The Cerro de la Concepcion at Valparaiso in Chili—Sir W. Mace's cases

of cholera caused by the opening up of a disused burial-ground in south India, and the spreading of cholera among railway workmen in India, after the funeral service—The Mahomedan cemeteries of Calcutta, which are a series for cholera, fever and dysentery—These are but a few of the many illustrations of the fact that the dead poison the living, which need only to be recalled to carry home a conviction of their truth. Our esteemed President can personally testify to the influence for well of the churchyard around St. George's Cathedral, Madras, and of a cemetery at Mayavaram.

If the physician of the future, the High Priest of the body, is to cease to be a tinker of the human frame, by developing into an officer of health, warding off disease, and annually increasing the percentage per thousand, of the population of centenarians, then in respect to burial he cannot too soon "cease to do evil"; and by adopting cremation, "learn to do well." The "philosopher's stone" and "perpetual motion" have long been the dream of the poet and the enthusiast, and many men, whose lives might otherwise have been useful, have wasted their time in these pursuits, till out of the ashes of failure, hygiene, or public health has arisen as the elixir of life. Burial is a sanitary evil.

Burial is unprofessional and a social sin. It is sinful to lay by poison for posterity, by thus sowing broadcast the seeds of disease and death. The pestilential germs which have destroyed the body are protected and treasured up so as to propagate and multiply, ready to reappear in time and work the ruin of others. The poisons of tubercular disease, anthrax or splenic fever, malarious disease, tetanus, scarlet fever, enteric fever, small-pox, diphtheria, malignant cholera, and yellow fever are all transmissible through the earth from the buried body, by more than one mode. These diseases are all preventible and destined to disappear at some future time. Why lengthen the lease of their life? Putrefaction affecting organic matter, disseminates the germs of fatal disease. "If each corpse is the bearer of millions of millions of organisms that are specifics of ill, what must a cemetery be, in which new foci are forming around each body? In the silence of death these worlds of organisms, invisible to the unassisted eye are laboring incessantly and unperceived, to fill more graves with more bodies destined for their food and for the fatal perpetuation of their species." Why hand down a heredity of preventible disease by preserving the germs which would be destroyed and stamped out by the high temperature required for cremation?

"PASTEUR'S researches on the part earthworms play, in bringing up to the surface of the soil the specific microbes of animals buried several feet deep, favors the above argument. In DARWIN'S paper read at the Geological Society of London in 1887, he proved that in all pasture land, every particle of the superficial layer of earth carrying different kinds of animal life, passed through the intestines of earthworms. The worms swallow earth matter, and after separating the digestible or serviceable portions, they spit the remainder in little mounds or heaps at the mouth of their burrows. In dry weather the water descends to a considerable depth and brings up to the

surface the particles which it ejects. This agency of earthworms is not so trivial as it might at first sight appear. By observations in different fields, Mr. Dawson proved in one case that a depth of more than three inches of this worm-mould had accumulated in fifteen years; and in another; that the earthworms had covered a bed of marl with their mould in eighty years to an average depth of thirteen inches."

"PASTEUR's researches on the etiology of *charbon* show that this earth-mould positively contains the specific germs which propagate the disease, and that the same specific germs are found within the intestines of the worm. The parasitic organism or bacteridium which inoculated from a diseased to a healthy animal, propagates the specific disease, may be destroyed by putrefaction after burial. But before this process has been completed, germs or spores may have been formed which will resist the putrefactive process for many years, and lie in a condition of latent life, like a grain of corn or any flower seed ready to germinate and communicate the specific disease. In a field in the Jura where a diseased cow had been buried two years before, at a depth of nearly seven feet, the surface earth not having been disturbed in the interval, PASTEUR found that the mould contained germs which introduced by inoculation into a guinea-pig, produced *charbon* and death. And further, if a worm be taken from an infected spot, the earth in the alimentary canal of the worm contains these spores or germs of *charbon*, which inoculated, propagate the disease. And the mould deposited on the surface by the worms, when dried into dust, is blown over the grass and plants on which the cattle feed, and may thus spread the disease. After various farming operations of tilling and harvest, PASTEUR has found the germs just over the graves of the diseased cattle, but not to any great distance. After rains or morning dews, the germs of *charbon* with a quantity of other germs were found about the neighbouring plants; and PASTEUR suggests that in cemeteries it is very possible that germs capable of propagating specific diseases of different kinds quite harmless to the earthworm may be carried to the surface of the soil ready to cause disease in the proper animals. The practical inferences in favor of cremation are so strong that in PASTEUR's own words "they need not be enforced."

Burial is uneconomical:—"London was computed by the census of 1871 to contain 3,254,260, of whom 80,430 died within the year. The amount of ashes and bone-earth such as is derived by perfect combustion belonging to, and buried with those persons, is by weight about 206,920 lbs. This bone-earth may be regarded as equivalent to at least six or seven times its weight of dried but unburned bones, as they ordinarily exist in commerce. The amount of other solid matters resolvable by burning into the gaseous food of plants, but rendered unavailable by burial, say for fifty or one hundred years or more, is about 50,564 lbs. The value of foreign bones whose importation was rendered necessary for purposes of manure, into the United Kingdom in consequence of the hoarding of British bones some six feet below the surface, was in:—

| | | |
|------|-----|-----------|
| 1868 | ... | 489,590 |
| 1869 | ... | 600,029 |
| 1871 | ... | 763,185." |

Further, each adult being entitled to four superficial yards of earth, and the common practice being the allotment of a quarter of an acre of burial-ground to each thousand of the population, the amount of waste and unproductive land or lands withdrawn from agriculture and purposes of food-production, and set apart for cometary purposes, is a grave commercial error. A serious consideration in cases of rapidly-growing towns and cities!

The grave is after all but a temporary resting-place. The soil fills with bones, houses crowd around, while the laws allow the re-opening of a grave after fourteen years. "Of 443 burial grounds, the London Metropolitan Public (Garden's) Association converted 116 into Railway lines, docks and streets; while others were converted into private gardens, play-grounds for schools, stone yards, builders' yards, stable yards or vacant building sites, tons of human *debris* being carted away. Thus burial does not, after all, ensure that "sweet sleep, calm rest," which the old prayer that the earth might lie lightly, has associated with the grave.

The horror of putrefaction, "the small cold worm that fretteth the enshrouded form," the notable revelation of horrors in church-yards made in "A Report on a General Scheme for Extra-Mural Sepulture (CLOWES and SONS: 1850)" and "A Special Inquiry into the Practice of Internment in Towns by EDWIN CHADWICK, (London, 1843)" are such as to make the mind revolt from the idea of burial. The books just named are replete with evidence, and should be read by those who possess any sentimental preference for the system of burial.

The statement that belief in the doctrines of the Christian religion necessitates the adoption of the system of burial, has no anchorage in the ocean of truth. Burial is nowhere enjoined in the Scriptures. The Hebrews hid their dead in caves because of the superstition current among them that the soul would revisit the body. MOSES nowhere legislates against cremation. The Rabbis admit that fires were kept burning in the valley of Tophet as a sanitary measure. In the Jewish church on April 10th 1894 we read:—"Cremation is not opposed to Jewish doctrine." The early Christians in consequence of persecution probably adopted the system of burial, because it could be performed in secret. Where but at a crematory can we most appropriately use the time-honored formula, "earth to earth, ashes to ashes?"

As SIR HENRY THOMPSON puts it: "The problem which Nature sets herself to work in disposing of dead animal matter is always one and the same. It may be thus stated. The animal must be resolved into:—

- (a) Carbonic acid (CO_2), water (H_2O), and ammonia (H_2N).
- (b) Mineral constituents, more or less oxidized elements of the earth's structure:—Lime, phosphorus and magnesia.

The first group, gaseous in form, goes into the atmosphere. The second group, ponderous and solid, remains where the body lies until dissolved and washed into the earth by rain. Burial is a contrivance to delay, though it can never prevent, the inevitable change. It does slowly, offensively, and dangerously, what cremation can accomplish in one hour without offence or danger."

Matter is indestructible and eternal. When the animal ceases to breathe, Nature demands the elements of his organism for the nourishing and beautifying of our vegetable progeny. Shall I hide my talent in a napkin and with truant-like reluctance delay in obeying her behests? I would rather joyfully hasten her work and anticipate her designs by gladly yielding up the carbon of my tissues to enter into the structure of the mahogany of a genial host, only in turn when the table becomes too old and is consumed, to enter into the composition of peas and cereals with which "to make glad the hearts" of the guest at another board, thus ever revolving in the harmonious cycle ordained by the Highest Economy.

What then shall we substitute for burial? I answer "cremation;" "cremate." Cremation is to burial, what the surgeon's knife is to gangrene. What Nature attempts to do slowly, imperfectly, and often dangerously, Science does quickly, thoroughly, and harmlessly. Burial is a process which essentially prolongs decay and putrefaction with all its attendant mischief; and the best that can be affirmed of it is, that in the course of many years, it arrives by a process which is antagonistic to the health of survivors, at results similar to, but less complete than cremation produces in an hour without injury to any. Avoiding the horrors of putrefaction and its attendant dangers, cremation arrives at the final constituents of gases and ashes. By burning, we arrive in one or two hours at the very stage of harmless result which burying requires years to produce. An adult body within two hours can be reduced to ashes weighing between three and four pounds. The aim of cremation is to prevent the process of putrefaction.

Fire, and especially the intense heat required for perfect combustion, is an efficient germicide. Cremation wipes out the presence and power of zymotic disease. Can there be a more effective plan for stamping out zymotic and other disease? This is the best treatment of the dead for the sake of the survivors. The land being for the living, not the dead, cremation will prolong life and make it more worth living.

It is economical. At Khulna, East Bengal, six maunds of fuel costing only one rupee eight annas, will completely consume a corpse. MR. FARRIE'S table gives the cost of a Hindoo funeral of the humbler class in the neighborhood of Poona according to COLONEL MARTIN, as twelve rupees seven annas and three pies, figures which appear to me to be rather high. Contrast with these figures, the cost of an ordinary *Christian* funeral in Calcutta! Cremation further frees the land for purposes of agriculture and food production.

The evil that men do, lives after them, the God is oft interred with their bones," sings SHAKESPEARE. This has its literal application in the case of the buried corpse; whereas in cremation, the man "ceases to do evil," and "learns to do well." The gases evolved go to build up vegetable life; while his ashes may manure mother-earth, form a brick or two of a room of his *alma mater*, or may even on occasion, serve as toothpowder to a MARK TWAIN on his travels! The field, however, is the proper destination for the ashes of a crematory.

Nothing is more pure, nothing less suggestive of decay or decomposition than the refined sublimates of a crematorium. No portion of refuse is left. The remains purified by fire and emblematic of a higher translation, may now be returned to the consecrated precincts of a beloved church, and add to the beauty of the edifice by being placed in early Egyptian, archaic Greek, transitional modern Greek, florid, semicircular, early pointed, geometrical, decorated, perpendicular, gothic, or ecclesiastical vases or urns deposited in Columbaria; or ancient crypts, or cloisters, on which the artist and the sculptor have lavished their utmost skill. Sentiment is satisfied. Mark the scene in the play of VIRGINIUS, where the vase containing the ashes of VIRGINIA is placed in the hands of the distracted father by the sorrowing lover! The Campo Santo—The Pyramids—The Castle of St. Angelo—The tomb of Cecilia Meletta—Westminster Abbey—and The Taj Mahal of Agra, are beautiful, suggestive and of historic interest. Why should not classical urns and columbaria attain to the same point of vantage?

Cremation eliminates the danger of premature burial, as in the case of a trance. Not to mention the preceding necessary inspection of the entire body the heat produced would render death instantaneous.

Cremation lends itself readily to the performance of religious and funeral rites.

Exhumation being only necessary to rectify the lack of adequate observation at a more fitting time, a well organised system of cremation will obviate this necessity. By burial, traces of morphia, atropine, aconite, strychnine, and prussic acid are sooner or later destroyed or associated with *ptomaines*, leaving only the metallic poisons, and of these practically only three, namely, arsenic, antimony, and mercury. By the appointment of officers to examine and to certify as to the cause of death, of district medical inspectors, and of a verifying central doctor (*medicin verificateur*) to whom reports of district medical inspectors are forwarded, and in consequence of the facility afforded for conserving at slight cost for years, the stomach and a portion of an internal organ in doubtful cases, the medico-legal objection against cremation resolves itself into an argument in its favor. Safeguarded by precautions, such as the illegalisation of cremation without medical certificate, to prevent the destruction of a body which might have met death by unfair means, there is no method of treatment of the dead which commends itself to my mind as superior to cremation. As Sir HENRY THOMPSON says: "Evil in the shape of disease and death resulting from the present system of burial, is infinitely larger than the evils caused by secret poisoning are or could be."

It would be well, however, till the world is wrought to fellowship with us in our beliefs, for the State to enforce the cremation of each and every body, the life of which has been destroyed by a contagious malady or a zymotic disease. This should be done in the interests of public health, and of generations yet unborn.

In the name of Custom which when noble, is ever elevating, but when foolish, is enslaving, and a fearful drag on individual and race progress. In the name of Sentiment, which the late laureate dignified by raising it into

fellowship with the dead when he says "for heart helps head;" and to which the refined sublimate of Crematory so beautifully lends itself. In the name of Crime, which needs an Argus-eyed detective, and in detecting which the due administration of the regulations, for regulations there must assuredly be, is characteristically capable at a very early stage. In the name of Economy which the Great Teacher impressed upon His followers when he bid them "gather up the fragments that nothing be lost." In the name of Rapidity which is so much needed in these days of varied energy and of keen competition. In the name of Simplicity, which has passed into proverb, "*ars est coelare artem*," the climax of art being the return to natural simplicity. In the name of Decency and Cleanliness, which we all so much admire, as to rank next to Godliness. In the name of Medicine, of which this will be a faithful pillar by securing the production of certificates of the cause of death in every case. In the name of Convenience, the ashes facilitating the payment of a tribute of grateful devotion at the shrine of the loved and lost. In the name of Utility, which directs the wheels of life so markedly that it has been said, and said with much approximation to truth, that "Man is a born Utilitarian." In the name of the Blood-Hounds let loose by war, and of which an ambulance furnace would be a mighty annihilator. In the name of Prophylaxis, which we all do so energetically extol in theory, but unfortunately too feebly practice. In the name of The Bacillary Origin of Disease, and those unseen enemies of ours, which cremation so successfully tackles. In the name of the Ills of Humanity, which are so multiplied, nursed and preserved by the most insensate method of burial. In the name of Fire the emblem of purity and power and the best of servants, which has so much to recommend it. In the name of Civilisation, which appears rotten to the core, and can boast of but an empty name, so long as we sacrifice principle to prejudice by countenancing such revolting results of the system of burial. In the name of Places, which have arisen to a consciousness of the burning importance of the question—and lastly, and as the climax of all, in the name of Sanitation, of which the physician of the future, The High Priest of the human frame, is to be a stern guardian, ceasing to be a "tinker of men's bodies," while he excels in noting and warding off the causes of disease, and in annually increasing the number of centenarians, I would earnestly entreat each member of the profession not to grant the subject of my paper a generous assent out of the amplitude of his philanthropy; but I would rather urge him to regard it as a natural and necessary outcome of scientific conviction, and a by no means unimportant element in the attainment of the climax of sanitary perfection.

—:—

THE SLEEPING SICKNESS OF TROPICAL AFRICA: SYMPTOMS, PATHOLOGY, ETIOLOGY, ANALOGUES AND TREATMENT.

By CHARLES FORBES, M.D., C.M., D.P.H.

THIS peculiar disorder is one of the marvels of West Africa. It has never, as far as I know, affected a European, and is limited to the negro race. Its ultimate tendency is

undoubtedly to death, although apparently, recoveries are recorded. It is certainly commoner among males than females. It may begin to attack the patient at almost any period of life, but is most usually seen in patients between the ages of 12 and 20. The patient succumbs little by little to feelings of somnolence which grow by gradations, gently, into a profound lethargy from which the patient (negro) may at first be roused, but only to sink back again into the same condition, which gradually gets more pronounced. The first perceptible symptom of this disease is a continual and persistent drooping of the eyelids (of man, woman or child) in the daytime, even while working; there is also enlargement of the lymphatic and cervical glands, especially the *glandula conoateata*, soon after the first onset. At this time the negro's health may appear to be quite usual, in spite of which, however, he gives way to fits of sleeping at the most unusual hours. In my opinion this condition should be combated at the very outset by energetic measures of stimulation and purgation; but the negro, though roused from the death-like slumber, is plunged back again into this soporific condition, each period of sleep becoming more protracted; they also slowly increase in number, and the intervals between them gradually grow shorter and shorter. This condition may go on for months, the malady gradually sapping the patient's strength, while at length the negro seems in truth, to be always asleep; his life now resembles that of the vegetable or fungus kingdom. This may last for weeks or months; meanwhile he refuses almost all the food which is offered him, and wastes his very life in sleep. His countenance gradually assumes a shrivelled-up look, progressive atrophy with emaciation sets in, and after a time, death from exhaustion or starvation supervenes at the close of about 3, 6 or 12 months. Here it may be noted that, just before death closes the scene, the inclination to lethargy is not so great, and the intellect seems to clear before the brain ceases to act. It is endemic only in Africa, and in that part which may be geographically described as being situated between the basins of the Senegal and the Congo on the West Coast, especially in the Sierra Leone district, and its Hinterland and the Congo district, where cases are more frequently met with and more virulent in their nature. This complaint occurs more frequently inland than on the coast line. Cases have been seen in the West Indies, &c., but only in negroes who have been transported thither as slaves from Sierra, Leone, Gambia or the Congo.

Pathology.—In considering this difficult and problematical subject: Poisoning by the continual inhibition of the malarial protozoon must be taken into consideration, especially its powerful effects on the neurotrophic system, thereby interfering intimately, by its own presence in the blood-current or by the production of toxins during its life by its own excretions of carbonic acid, &c., or by its breaking up of the red blood-cells and hemoglobin, their coloring into methemoglobin and other bye-products of chemical decomposition, which are at present ill understood. DR. HENRICH says something apropos of this in a paper on "Malarial Malanemias" in the *Indian Medical Gazette*, 7th July 1894, page 247, and states that LAYBURN was the first to notice blood pigment free in the blood of patients suffering from paludism, however "*sed ad rem*," as CROUS says in his

positions when he has digressed from the main point. No matter how it is caused, malarial poisoning has a profound influence for ill on the nutrition of the body. I will now, in a few words, note down the results of a few *post-mortem* examinations on these patients who have fallen victims to its fatal influence. The following morbid changes are visible to the naked eye, *viz.*, hyperæmia of the arachnoid membrane with slight signs of chronic inflammation in the other meninges (*pia and dura mater*). In spite of the above facts, we find no special accumulation or collection of fluid in the ventricles of the brain or external to it in the subarachnoid space, &c. One very noteworthy circumstance is, that the brain substance in every case is somewhat paler than normal, pointing to existent anæmia of the cortical centres. The *spleen* was enlarged in one of my cases, but this was due, I think, to malarial taint. The enlargement of the cervical glands was well marked in every case. There was seen on section of these glands increased formation of connective tissue elements and atrophy of active gland cells. In two cases examination of the blood showed the presence of *filarie sanguinis hominis*—major and minor; but the presence of these parasites must be deemed adventitious, as they occur also in other countries and other diseases. Dr. MANSON reports a case of mummery elephantiasis from the South Sea islands, in whose blood the *filaria nocturna* was present—see *British Medical Journal*, 2nd June 1894, page 1186.

Dr. STEPHEN MACKENZIE showed a patient (see *Lancet*, 22nd November 1890) whose blood, he said, when examined, displayed specimens in number, of *filarie sanguinis hominis*, both diurna and nocturna. Dr. MANSON also discusses this subject further in *Lancet*, 1st October 1892, and again in DAVIDSON'S "Diseases of Warm Climates," 1893."

Cases, however, have been seen and noted in which patients with organic lesions of brain-tissue have seemed to acquire the characteristics of Congo sleeping sickness, as this mysterious disorder has been wrongly termed.

Etiology.—The causative factor or factors of this "marvellous disorder," which is a sort "of death in life," has not yet been satisfactorily established, and so its *defacto* origin appears wrapped up in several obscure problems. Several authors have endeavoured to clear this matter up with the most indifferent and uncertain results. One suggestion was propounded as follows: that it might possibly arise from ingestion of a fungus which grows on certain grains habitually used by the natives as food in the shape of "Kakee," which means bread, &c. However this may be, no proof is forthcoming of its verification. The Gordian knot of the difficulty has not yet been cut, and the problems are still unsolved. Another fact may here be stated is, that neither change of residence or diet suffices to interrupt the steady progress of the symptoms to a fatal issue. The following theories are perhaps the most acceptable from a medical point of view, *viz.*—*Firstly*, that it may be due to a strongly septic condition of the blood, this is partially borne out by the swelling of the glands and degenerative changes taking place in them. *Secondly*—May it be due, as Dr. MACKENZIE seemed to think, to the presence of *filarie sanguinis hominis* of both kinds—nocturna and diurna germs in the blood. There is nothing to prove this

save the fact that these filarious germs have been met with in the blood of perhaps no more than half a dozen patients afflicted with "sleeping sickness." But, at the same time, these parasites have never been reported as found in white men suffering from somnolence, &c., &c.

Thirdly.—It may be a neurosis tending to final establishment of cerebral anæmia, and imperfect nutrition of certain centres, such as the pituitary body, and eventually affecting the trophic system causing somnolence, with ultimate progressive emaciation and death. This latter is my theory, but it is assumption merely and not proven.

Diagnosis should be easy from trance, GAYET'S disease, GERLIEN'S and WERNICKE'S disease and cases of somnolence such as those mentioned by Dr. MILLS in the *Canadian Medical Record*. As sleeping sickness proper, attacks only negroes, but these other complaints are found among white people, and shew a low state with defective intelligence, etc, approaching nearly to the animal kingdom.

Prognosis is very bad, most cases are inevitably fatal, especially those met with around the Congo, and when once the complaint seizes the patient, it tends to be actively progressive in its course (despite the most skilful and energetic treatment), to a fatal termination. Among French medical men in West Africa, GUIRIN reports 148 cases, all of which proved fatal at various periods. GORE'S statistics drawn from Sierra Leone and the neighbourhood, estimate the mortality at about 80 per cent. which is too favorable an average even for that region. Personally I have had experience of only 13 cases treated by myself, eleven of these died between six and 12 months after being seen. Two however survived for a period of 18 months, but whether they afterwards relapsed or not I had no data beyond this point to assist me in determining.

Its Analogues.—I will now draw attention to some rare and curious diseases met with in Europe, but I have no space to discuss them here. I mean (1) GAYET'S disease; (2) GERLIEN'S disease or summer somnolence of Switzerland; (3) cases of lethargy among white people, such as the three reported by Dr. MILLS in the *Canadian Medical Record*. The only points the above diseases have in common with African lethargy, are the somnolent symptoms. (4) WERNICKE'S disease, which shows similar symptoms to the above disorders, and morbid processes producing lesions of the corpora quadrigemina. (5). There is a disease met with at Rio (South America) in which there is a tendency to sleepiness gradually deepening to lethargy or coma due to a septic condition of the blood, but accompanied by pyrexia and secondary changes in the brain. The question to be settled is—Does the blood of these patients contain *filarie sanguinis hominis* or other filarie as in the cases of malignant lymphangitis met with at Rio? If so, this disease would go far to establish the cause of lethargy at Rio if not elsewhere.

Treatment.—This of course, is only tentative and somewhat empiric in its rationale, as we are in the dark as to the true cause of the disease. I will therefore make a brief statement of the remedies which from personal experience of their value, have proved to be the most applicable in all tropical countries and diseases. At the onset administer two compound cathartic pills at bed-time. Repeating the

(2) *What is its pathology?* The pathological fault in diabetes is, as you are aware, that the carbohydrate food, instead of being retained and utilized in the system as in health, runs off the body through the kidneys in the form of sugar. In India is it due to a faulty condition of the liver, or is the lesion to be found in the pancreas? Are Indian physicians ready to accept Dr. PAVY's recently started protoplasmic theory? Might not the facts, that mental worry so frequently acts as an etiological factor in diabetes, and also that tumours and diseases of the brain, punctures of the floor of the fourth ventricle, destruction of the various sympathetic ganglia and section of the anterior cervical nerve roots induce glycosuria, be considered in accepting diabetes either as a brain disease or a neurosis?

(3). Is the disease more prevalent in India than before?

(4). What influence have age, race and profession on the disease?

(5). *Its causes.*—Has it any connection with nervous strain, alcoholic drink, early or excessive sexual indulgence, ingestion of excessive starchy and saccharine food, heavy brain work and bad nourishment, high thinking and free living as opposed to high thinking and plain living? Does gout or gouty diathesis predispose towards the disease? We can understand how in Europe highly nitrogenous food and wine produce gout, and through what organ, and how the pathological process is started, but we are unable to follow how ingestion of carbohydrates and saccharine food in default of well-regulated muscular energy produce diabetes.

(6). *Clinical features.*—Does a case of diabetes run the same course and present the same symptoms in India as in Europe? Do we find here the acute glycosuria in the young and the chronic in those more advanced in life? Do we find in India cases that are of mild glycosuria amenable to modified diet? Are the classical symptoms such as polyuria, thirst, burning sensation of the body, causalgia in the feet always present?

(7). *Diet best suited.*—Is it advisable in a hot country like India to confine the diet entirely to albuminates and fats? A diabetic always retains a certain amount of power to metabolize carbohydrates and utilize sugar, and if these articles of food are entirely cut off, does not his system suffer?

(8). *Prognosis.*—Is diabetes curable? If sugar be detected in the urine, does that life become unfit for insurance?

A printed schedule of questions to be answered by each patient has been prepared by me for the guidance of the physician. I append herewith an analysis of 200 cases:—

1. *Sex.*—Two European patients say that their mothers died of diabetes. I believe diabetes is extremely rare among females in India.

2. *Race.*—My 200 cases are thus classified:—

Europeans, 9; Eurasians, 5; *Hindus*:—Bengalee, 47; Madrassae, 8; N.-W.P., 16; Punjabi, 12; other parts of India, 52; *Muhamedans*:—Bengalee, 9; Panjabi, 13; other parts of India, 22; Sikhs, 2; Parsees, 4; *Christians*:—Bengalee, 5; Madrassae, 1.

3. *Profession.*—The following shows the profession of 200 cases:—

Lawyers (including judicial officers), 43; medical men, 18; school masters, 7; merchants, 12; engineers, 5; retired Government servants, 5; journalists, 2; mariners, 1; soldier, 1; clerks, 15; no profession, 90.

4. *Age.*—In the majority of my cases the age in which the disease was first noticed was between 35 and 55. In India we see a large number of cases of diabetes occurring in old age after 55. These cases usually run a mild course.

5. *Family history.*—Out of 200 cases, 95 give a distinct history of heredity. In 8 cases there is a history of a diabetic brother, but not of diabetic parents. In two cases, mothers died of diabetes.

6. Married 188, unmarried 12. Of the ages at which marriages took place, I find not more than ten under 20.

7. In a large majority of cases, one or two years after the onset of severe symptoms the power of procreation ceased. In mild cases, however, sexual power was unimpaired and semen retained its fructifying virility. One patient says he had 5 children after the onset of the disease, which was by no means a mild attack.

8. Many patients are sedentary in their habits and their number is larger in comparison with those whose habits are active.

9. Intemperate, 4; temperate, 107; total abstainers, 89. It will be seen that total abstainers in India are by no means exempt from the disease.

10. Out of 200 patients, 69 use opium habitually, one of them taking 20 grains daily.

11. In the majority of patients great emaciation and loss of weight followed the disease. In a very few cases no marked emaciation followed. One patient's face and extremities wasted, but his abdomen remained as obese as before.

12. It is to be noted that whenever patients have to perform any extra mental labor, such as writing, the symptoms are always aggravated.

13. Many patients fail to trace the disease to any grave mental anxiety, while 27 attribute their illness to family affliction, grave mental anxiety, or grief, or collapse of a lucrative business.

14. In 2 cases out of 200 there is a history of injury over the head.

15. The majority of patients say that their usual diet before the disease was noticed, was an ordinary mixed one. Twelve patients have always been strict vegetarians. No patient admits that he was exceptionally fond of sugar.

16. Various intercurrent maladies are reported. Acid dyspepsia is a common complaint. Rheumatism, haemorrhoids, phthisis pulmonalis, and chronic bronchial asthma, are other complaints that are found in some diabetics. Twelve patients are subject to malaria, 5 are gouty. Syphilis occurs in 6.

17. In one case the medical attendant says that the disease was first ushered in after a chill following a severe drenching in rain, which threw the whole body in a condition of aches and pains; this, with an unusual desire to urinate frequently and an insatiable thirst with constant dryness of mouth and throat, made the patient seek for medical aid, when sugar in the urine was detected. In one case the disease appeared after an attack of remittent fever, and then became a confirmed malady. In 3, after acute rheumatic fever.

18. Polyuria is almost universally present. It is however conspicuous by its absence in 8 cases. The symptoms

is usually intermittent. One patient says he passes 4 gallons of water daily.

19. The average quantity of sugar estimated is from 8 to 10 per cent. The specific gravity in 9 cases appears to be below 1.020. The highest is 1.050. A trace of albumen is recorded in 12 instances (most of these are patients of old age). The reaction is acid in all cases.

20. Thirst, burning sensation over the body, and sleeplessness are present, more or less almost in every case.

21. Diabetics in India very rarely follow a strict anti-diabetic regimen. In a tropical country it becomes almost impossible to restrict the diet entirely to meat and fat. A Bengalee usually cuts down his rice to a minimum and takes to wheat or bran. A Punjabi leaves off wheat flour and takes to bran. A European begins to take bran bread, but a strictly exclusive diet, as it is understood in Europe, is very seldom adopted in India. Many patients say that bread, wheat or bran, does not agree with them; the former increases thirst and acidity and the latter produces dyspepsia. Several patients speak highly of fruits.

22. Skimmed milk was tried by 185 cases. Two patients speak very highly of it, but from the majority of cases in which it was tried, it appears that beyond assuaging thirst, and perhaps relieving the burning sensations of the body, no other result follows its use. Large quantities appear to act as a flushing agent, just as large quantities of alkaline mineral water do.

23. No drug appears to have any appreciable value in a case of confirmed diabetes. *Opium* has been given a trial by nearly every patient whose history I possess. There are some who speak very highly of it, while others have found no relief. *Codeia*, I find, was tried in 120 cases out of 200, and the result is the same as with opium. *Jambul* has been tried by a large number of patients with no definite result.

In 23 cases *arsenic* was tried with scarcely any appreciable result; temporary benefit was however obtained by the use of the drug. *Alkalies* and alkaline mineral waters are highly spoken of by those who have used them. Bromides of arsenic, soda, potash and lithia, antipyrin, sulphonal, salicylic acid, salol, pancreatic emulsion, and raw pancreas were the other remedial agents tried with scarcely any marked improvement. One patient avers that he derived great benefit from the ash of burnt *sandri* wood.

24. Climate seems to improve the general health, and with such improvement the symptoms usually abate.

In summer a sojourn to a cooler clime proved of great benefit to several patients. Sea air was tried by 4 patients who say that it produced remarkably good results on their general health.

25. Skin diseases, boils, carbuncles and cataract are complications in most cases. Cardiac weakness is complained of in 2 instances. Erythema on hands and feet occurs in 4 cases. One patient has eczema. Constipation is the usual complaint. In 3 cases, oedema of the feet and hands is present.

EMPHYEMA.

No operation is justifiable unless the presence of pus is certain; unless thorough treatment by medicinal agents, blisters, etc., has failed; or unless the symptoms dyspnoea, etc., are so urgent as to demand immediate relief. (And the only way to be sure of the presence of pus is by the use of the aspirating needle).—*ASHMUSSEN*.

A MIRROR OF PRACTICE.

TWO CASES OF SUCCESSFUL OVARIOTOMY.

By EDWARD BARK, C.M.S. (Hyd.),

District Surgeon, Parbhani, Hyderabad, Deccan.

CASE I.—*Ameeoonissa Begum*, *et. 50*, was admitted into the hospital on the morning of the 24th of November with a distended abdomen. The case was diagnosed as one of ovarian dropsy.

At 8-30 A.M. the operation began. The abdominal wall was well washed with carbolic lotion (1—40) and then the patient was put under chloroform. An incision about 1½ inches in length was made in the linea alba, two inches below the umbilicus. The peritoneum having been opened, the cyst was found to be a multilocular one, adherent to the liver and omentum. The fluid (45 pints) was emptied and adhesions carefully freed. A few of the bleeding points were secured by pressure forceps and tied, the pedicle was ligatured with thick silk, and the cystic growth excised. The abdominal cavity was then washed out with a solution of carbolic acid (1—100), the edges of the wound being brought together by horse-hair sutures; lastly, the wound was painted over with antiseptic ointment (2 grs. of double cyanide of mercury to the oz. of collodion).

The patient had been suffering from prolapsus uteri for the last two months, due to the weight of the fluid, but soon after operation the organ was replaced spontaneously.

After operation (11-30 A.M.) the patient was ordered half an ounce of brandy in water, her condition being low.

She was kept on milk and broth throughout. At 1 P.M. the bladder was emptied by a catheter, and at 4 P.M. a turpentine enema (oil of turpentine 5j, warm water, Oj) was given, the bowels acting freely. At 6 P.M. the patient complained of a little abdominal pain and tenderness, and at 9 P.M. she was ordered a pill containing 2 grs. of opium and ½ gr. of extract of belladonna. She slept soundly for four hours.

The next day there was very little abdominal pain, but a troublesome cough set in. The temperature was normal. The turpentine enema was repeated and a pot. iodid mixture given internally. At bed-time an opium pill was administered. From this point, the patient progressed favorably; for her cough, ipecac and morphia lozenges were continued for one week, and the turpentine enema, until 2nd December (8 days). On 4th December the sutures were removed, strips of sticking-plaster being applied across the wound, and the whole secured by means of a binder.

On 10th December the patient, who had not menstruated for the last two years, (*i. e.* since the onset of the disease), began her menses, which ceased on the 18th. She was discharged cured, on 15th December.

Remarks.—(1) The incision was a little less than 1½ inches in length, and though this is far too small, I explored the whole of the abdominal cavity with my index and middle fingers, freeing adhesions as they occurred.

A long incision is undoubtedly more advantageous, but the risks of peritonitis are equally greater.

(2). The wound healed by first intention; the temperature throughout being normal.

(3). I performed this operation, as above, with the assistance of only a compounder and two hospital coolies.

CASE II.—Bhoomalai, *et. 22*, caste Brahmin, states that 24 years ago, she noticed a swelling as big as a hen's egg in her left side (left iliac fossa) accompanied by pain, and that this swelling gradually increased in size. She was partially tapped by one of the military surgeons of Hingoli six months ago, and after tapping, the abdomen contained some bag-like processes. Eight days after tapping it began to enlarge, and within a month it resumed its former size. There was cessation of menstruation at the commencement, but five months after the growth began, till now, menstruation has been regular.

Present condition.—The patient is fairly well nourished; temperature and pulse normal; skin normal; respiration 28 per minute. The heart, liver and kidneys are healthy. In the supine position a roundness is observed, and the surface of the abdomen is uniformly dull, the area of dullness not being altered by position. Fluctuation is limited, and not superficial; there is no oedema of the feet or eyelids. The patient is suffering from chronic bronchitis in addition.

Diagnosis.—The case was diagnosed as an ovarian cyst.

Treatment and progress.—Three days prior to the operation, the patient's bowels were kept open by colocynth pills and turpentine enemata. At 12-45 p.m. her bladder was emptied by a catheter, and exactly at 1 p.m. the operation began.

Description of operation.—The patient's abdomen was well washed with soap and warm water, and then with a solution of carbolic acid (1-40), and antiseptic towels were laid on her thighs and abdomen. She was placed under chloroform, and an incision about 4 inches in length was made in the linea alba from about an inch below the umbilicus. The bleeding was then controlled by pressure forceps and the part well sponged. The peritoneum was then laid open and the cyst discovered to be adherent to it. The fluid was evacuated from the principal cyst, and it was then found that this cyst was also adherent, but to the whole of the abdominal and pelvic walls, extending as high as the liver and spleen: (the uterus, however, was free from adhesions.) These adhesions were carefully freed, and all bleeding stopped. Two other cysts were then emptied out, the pedicle was ligatured with double silk, and the cystic growth delivered. The abdominal cavity was well sponged, and was then washed out with a warm solution of borax, and next with a solution of carbolic acid (1-100). The edges of the wound were brought together by horse-hair sutures, and the wound painted over with antiseptic collodion. At 3-45 p.m. the operation ended.

Description of tumour.—It was a multilocular tumour, semi-solid in nature. The principal cyst contained a thick sanguineous fluid while the smaller ones, a fluid resembling boiled arrowroot; the quantity of fluid removed was 26 pints.

Treatment.—At 5 p.m. the patient vomited and 10 grains of oxalate of cerium were given, which stopped it. At 7 p.m. an enema of turpentine was given, but the water did not return; the patient had a violent cough, and complained

of a little pain in the abdomen; there was no tenderness or puffiness of the abdomen. From 8 to 9 p.m. she slept well. At 10 p.m. 2 grains of opium and 1 grain of the extract of belladonna were given in a pill. She slept till 1 p.m. Four ounces of milk were administered at this hour.

The next day there was only a trifling amount of abdominal pain, but no tenderness. The temperature was 98.2, but her cough was very troublesome. For this an antimony and paregoric mixture were given her. The turpentine enema was repeated, but without effect.

From the 8th January (the second day after operation) onwards until the 11th, the temperature fluctuated between 102.6°F. and 100°F. The cough was very troublesome, and there was a good deal of vomiting, especially at the sight of milk, which was controlled by oxalate of cerium. On the 10th she passed a round worm after the turpentine enema was administered, and thereafter progressed well. One suture was removed on the 11th and two more the next day. The wound discharged somewhat, but healed steadily by granulation, being dressed with carbolic oil. All sutures were removed on the 20th and sticking plaster applied to the wound.

She was discharged cured on the 31st, that is, 25 days after operation.

Remarks.—The adhesions were very extensive and intimate. The tumour was adherent to the whole of the abdominal and pelvic walls, and to the liver and spleen. I ascribe this to the operation of tapping six months previously, and the positive harm that arises from tapping can thus be imagined. There were no posterior adhesions.

EPITHELIOMA OF PENIS.

By RAI BAHADUR M. N. OHDEKAR, L.M.S.,

Assistant Surgeon, Allahabad.

CASES of epithelioma of the penis are more often met with than they were a few years back. Either the number of cases of this disease are actually increasing, or the increase is only apparent owing to patients availing themselves more largely of the English method of treatment. It is probable that a great many cases in former years died a slow death at their village homes and never applied for that relief which surgery alone held out to them. The disease is more common among the rural population, and is very rarely met with in people of easy circumstances. It is also chiefly found among the Hindus. I have never seen a case among the Mahomedans. The immunity among Mahomedans is, I believe, due to their old custom of circumcision. Want of cleanliness appears to be the chief factor in the causation of this disease.

A few years back only those cases were considered fit for operation in which the disease was either confined to the glans or to the glands and a small portion of the body, and those in which there was no chance of going sufficiently beyond the diseased tissues, and of leaving a stump in front of the scrotum were considered incurable, and sent away. The result of the cases operated on was not very satisfactory, as combination of the medical and surgical generally followed, and recurrence of the disease was far from uncommon. Goorah, however, has introduced a method of operation by which a surgeon can now vary

confidently take in hand cases formerly considered beyond the pale of surgery. The result of the operation is eminently satisfactory, as it enables one to go well beyond the diseased tissues. No urinary troubles follow, there being no danger of contraction of the urethral orifice, and the chances of recurrence of the disease after operation by GOULD's method, are exceptional.

The operation itself is a simple one, and is performed by dividing the scrotum into two halves by an incision running along the centre line and terminating at the perineum, about an inch or an inch and-a-half from the anal orifice. A circular incision is next made round the root of the penis, which is then dissected down to the level of the symphysis. The urethra is next carefully dissected, and a director being passed between it and the corpora cavernosa, it is divided in such a way, that when brought to the lower angle of the incision, it might project about $\frac{1}{4}$ or $\frac{1}{2}$ of an inch beyond the surface of the skin. The penis is now taken hold of and removed with one sweep of the knife on a level with the ascending ramus of the pubis. No retraction takes place, and the hæmorrhage can be controlled by pressure of the thumb, until ligatures are put on.

A question now arises as to whether the testes should be left in or removed. If they are at all enlarged or in any way diseased, or if any portion of the scrotum is also affected with epithelioma, I remove them; but if the skin is healthy and the testes of normal size, I leave them. I am, however, inclined to think that it would be better to remove them and the greater part of the scrotum in every case, as the penis being removed, the testes form a useless encumbrance. All the cases in which I removed them made a more rapid recovery than those in which they were left in. The removal of the testes prolongs the operation, and the decision in each case will depend greatly on the constitution of the patient and his capability to bear the shock of the additional operation.

The bleeding points having been secured, the wound should be carefully washed with an antiseptic lotion, and the urethra secured at its lower angle by means of a couple of catgut or horse-hair sutures. The wound is then dusted with iodoform, a drainage tube laid along the entire length of it, and the edges brought together by horse-hair sutures. Two or three silver-wire sutures may be put in for greater support. The wound heals rapidly, and the result is all that a surgeon can desire.

TWO RARE RECOVERIES IN MIDWIFERY PRACTICE.

By C. A. THORNMAN.

Civil Hospital Assistant, Tellicherry.

CASE I.—A middle aged Hindu female, who had had nine previous normal confinements, took ill this time with *tertius mæri*, after dilatation of the os and rupture of membranes. The labor was prolonged for six days, during which time the village *dhat* attended on the patient.

The village was six miles away from my dispensary, and on arrival at the patient's house, I met satisfaction. The patient was a *shamul*, among Hindus, is the ill vented, small room of her home, stretched on a bare mat

on the damp floor, her body pale, except at the hips, pallid appearance, cold and clammy extremities, imperceptible pulse, quick and gasping respirations, and was almost unconscious.

Some hot milk was at once ordered to be given gently by an assistant, and on examination, the os was found fully dilated, head presenting, with an aperture, and separation of skull-bones, which easily came away piecemeal, as putrefaction had set in at least 24 hours ago. With the blunt hook and a hand in the vagina, the neck and body of the fetus were brought forward, getting the nearest arm out; a great deal of force had to be used in extracting the body owing to its being swollen by putrefaction.

The placenta was *darkish* in color and shrunk. A single, weak antiseptic injection immediately after the operation, and a few doses of quinine and chlorate of potash with stimulants along with a fairly nutritious diet for a few subsequent days, and iron afterwards, effectually brought her round from a moribund state.

CASE II.—A young Hindu female, near the same village, whose first confinement was difficult, and managed by native midwives, and who suffered from vesico-vaginal fistula ever since, was brought with labor pains to the hospital during the eighth month of her second pregnancy, two years after the first; the pains continuing beyond the usual time, without progress of labor.

The Civil Surgeon, assisted by his hospital assistants and a diplomed midwife, found a cartilaginous fibrous band across the os externum, which was divided. Some caloral hydras given, and not seeing the least dilatation of the os after a few hours, though regular pains continued, the cervix feeling cartilaginous, chloroform was administered and five radiating incisions, each an inch long, were made, dividing the cartilaginous portion of the cervix, and the dead fetus was extracted by the foot, the patient making a satisfactory progress in hospital afterwards.

THE CONTAGIOUSNESS OF LEPROSY.

It appears now to be generally admitted by those who have had the greatest experience amongst cases of leprosy, that the disease is distinctly contagious, and that it will in course of years infect a whole district; its progress being so slow, and the period of infection so prolonged that once it has commenced to spread it is almost impossible to predict the ravages which it may commit; and all observers appear to be united in the advice that as soon as a case of leprosy is discovered, it should be firmly and finally isolated, and access from the healthy to the diseased should be rigorously forbidden. It appears to be, in fact, disease dependent rather upon actual contact than any other method of infection. The effects of isolation are beyond all dispute, and in Norway, for example, in twenty years, the number of cases suffering from the disease was reduced from more than 2800 to less than 800 by the compulsory segregation of lepers. It would appear that the disease is increasing in the United States, because it has now been proposed, there, that neglect on the part of a medical man or any relation to report the appearance of leprosy in any person, shall be regarded as a penal offence; that immigrants affected by leprosy should be arranged at the ports of entry and sent home again, and that the Government should establish graded Hospitals where both confirmed, and also suspected cases may be carefully isolated and treated.

OUR PICTURE GALLERY.

RAI TARAPRASANNA ROY BAHADUR, L.M.S.,

F.C.S., F.I.C., F.U.C.,

Chemical Examiner to the Government of India.

By CHUNI LAL BOSE, M.B., F.C.S.

RAI TARAPRASANNA ROY BAHADUR was born in Calcutta, in the year 1844, in the house of his maternal uncle BABU MADEB CHUNDER SEN.

His father, the late BABU SARODA PRASAD ROY, who was an assistant in the Bank of Bengal, belonged to a respectable and well-known Baidya family in Kanohraparah.

Dr. ROY is connected by family ties with several well-known Baidya families related on his mother's side to the Sen family of Oolostolah, the family to which the celebrated KESHUR CHUNDER SEN belonged. Several other members also of this family, though hardly so well-known as KESHUR CHUNDER SEN, were men of considerable merit and acquired positions of trust and responsibility.

Dr. ROY was educated at the Hare School, from which he proceeded in due course to the Calcutta Medical College. His College career lasted the usual period of time, and was of a decidedly brilliant nature; for he won numerous medals and prizes and succeeded in acquiring not only the approbation but also the confidence of the professors. Of this a very signal proof was given by the fact that while still only a senior student, TARAPRASANNA ROY was permitted to act for two months as DR. PARTRIDGE'S House Surgeon in the Medical College Hospital.

Professor BOWEN PARTRIDGE acknowledged his appreciation of young TARAPRASANNA ROY'S work in the following terms:—

"During the time that Babu TARAPRASANNA ROY has acted as assistant in my ward, he has fully maintained the reputation which he had previously earned for himself in the College. As a student, he has been most distinguished, having carried off many of the College prizes, and having in the first examination in Medicine of the Calcutta University, obtained the University scholarship in Physiology and Comparative Anatomy. As my assistant, he has shown that he is not merely a reader but a worker."

At the final examination, which he passed in 1867, DR. TARAPRASANNA ROY stood first. He was awarded University honors in Medicine and obtained thereby a scholarship of Rs. 40 monthly, tenable for two years. After qualifying he entered Government service, and in January 1868 was posted as House Surgeon to the Calcutta Eye Infirmary under Dr. CHARLES MACNAMARA.

After two years' work in the Eye Infirmary he accepted the appointment of Assistant Professor of Chemistry under Dr. F. N. MACNAMARA, who was then Chemical Examiner to Government. This was in 1869, and from that time until his retirement, (due to ill health,) in March 1894—a period of about 24 years—Dr. TARAPRASANNA ROY worked continuously in the Government Analytical Laboratory in Calcutta.

As already stated, his first appointment was that of Assistant Professor; in 1875, he became Assistant Chemical Examiner in addition to his other duties, and in 1876,

Additional Chemical Examiner. This appointment under the title of "Chemical Examiner to Government," he held up to the date of his retirement.

The earlier years of his service were thus associated with the two MACNAMARA'S, for both of whom he has always cherished the greatest admiration and esteem. That these feelings are deep and sincere, any one who talks over old times with Dr. TARAPRASANNA ROY cannot fail to discover, and that the esteem was mutual, will be evident from the following interesting letter written twenty years ago. Dr. C. MACNAMARA thus wrote in 1874:—

"BABU TARAPRASANNA ROY was for some years my assistant at the Calcutta Eye Infirmary, and I formed the very highest opinion of his ability, industry and integrity, in fact I cannot speak too highly of him."

On several occasions, Dr. TARAPRASANNA ROY officiated as Chemical Examiner to Government, and during 1877 acted as Lecturer on Chemistry and Medical Jurisprudence at the Campbell Medical School. He was an Honorary Lecturer on Chemistry to the Indian Association for the Cultivation of Science, and for many years has been Analyst to the Oriental Gas Company, Limited.

In 1884, a medal was awarded to Dr. ROY by the Committee of the International Exhibition held in Calcutta in that year, for the valuable collection of indigenous poisons which he had contributed.

His scientific attainments have, in addition, been recognized by English Chemical societies. For he was elected a Fellow of the Chemical Society, London, and a Fellow of the Chemical Institute of Great Britain. The latter distinction is enjoyed by only a very few of his fellow countrymen. Dr. TARAPRASANNA ROY was also a Fellow of the Calcutta University. In 1889 Dr. ROY'S services were signalized by the distinction of *Rai Bahadur* being conferred upon him.

In 1868 the onerous and unhealthy nature of the work which obliged him to pass six hours daily in a vitiated atmosphere, began to tell upon Dr. ROY'S health. He broke down and was obliged to take a year's furlough. Rejoining in 1869, he discharged his duties for the next 5 years, but again became so seriously ill, that he was compelled to retire on pension in March 1894, which, let us hope, he may live to enjoy for many years to come.

HEART FAILURE AND TYPHOID.

THE treatment of the progressively failing heart in typhoid fever should consist of the administration of strychnia in full doses hypodermatically. The use of this drug in medium doses during the early stages of the disease will do much, I believe, to keep up cardiac tone and thus prevent the anæmic condition of the later stages. Alcohol freely used will tide the weakened heart over the interval of severest strain. I think alcoholics should be withheld in the disease until the time of cardiac weakness and then should be given in full doses. Caffeine, camphor and ammonia have their place when stimulation is most necessary. Digitalis is of doubtful benefit to an already overworked heart. Other remedies are sulphuric acid tar and potassium bichromate. The mixing of these substances must, of course, be done cautiously. Pulverize the bichromate, and triturate the tar with it; then gradually add the sulphuric acid, agitating continually with a glass rod, the entire operation being done in a well ventilated place. Let it stand until all reaction is terminated.—*Ballard's Medical Journal.*

Yours sincerely
Napassamashoe

THE Indian Medical Record

1st June, 1895.

THE SERIOUS DEFECTS OF THE STATION HOSPITAL SYSTEM IN INDIA.

It is pleasing to find an officer, whose opinions are entitled to respectful consideration, at last condemning a system which should not have been permitted to have been on its trial half as long as it has been. Brigade-Surgeon HILL-CLIMO, in an article contributed to the *United Service Magazine*, blames, indirectly at least, the station hospital system of medical relief for the European army in India, and for the annually increasing prevalence of enteric fever and mortality therefrom. The station hospital system has had one great fascination—a charm which it appears impossible for the authorities to resist—it is economical compared with the old regimental system, and to this charm principally does it owe, not only its introduction and adoption, but also its fairly long existence. The medical staff, thirsting to exercise military command, and yearning for emancipation from regimental control and authority, painted the system in the most enrapturing colors; the medical staff ever since has adopted it as its own begotten child, and has been ever solicitous to overlook its defects and to blind all others to its shortcomings. DR. HILL-CLIMO looks beyond himself and the convenience of the service to which he belonged; and now that he has retired from the army, points to some disastrous conditions which have resulted from the abolition of the system of appointing medical officers to *regiments*. We do not know why DR. HILL-CLIMO waited until he retired from the service of the State to give the State the benefit of his opinion and experience of the station hospital system, or rather of the abolition of the regimental system. Probably he felt himself gagged while in the service, and had to bottle up all his convictions at any cost. It may be, too, that he hoped that more weight and authority would be given to his utterances if backed by the accumulated personal experience of as many years as possible of "effective" service. Under any circumstances, we are thankful to him for having endeavoured to open the eyes of his medical brethren, who have hitherto continued to be blindly infatuated with a system which removes them from a certain amount of military restraint and disciplinary control. DR. HILL-CLIMO is convinced that the increase from year to year in the admissions and mortality from enteric fever are due to the insanitary condition of our Indian cantonments; that such insanitation has resulted from a want of skilled inspection of regimental lines; and that this last result is the consequence of regiments not having medical officers serving with them. DR. HILL-CLIMO traces this decline in the sanitation of regimental lines to the Afghan War of 1879, when cantonments were fouled by large bodies of troops, transport, and followers passing through them. We feel sure, however, that this fever-prevalence is to be traced back to two or three years before the Afghan War. Fever was distinctly on the increase everywhere in India immediately after the famine of 1877 began. Military cantonments, which

were previously remarkable for their healthiness, grew to be remarkably malarial. The famine of 1877 made the first large contribution of impure air in sanitary surroundings, and fever-causing material, which wars and expeditions have since added materially to. Whatever may be the cause and origin of the deterioration in the sanitary condition of Indian cantonments, the introduction of the station hospital system appears to have been the very worst system that could have been adopted for the removal of the sanitary defects. As DR. CLIMO says: "At the very time that regimental sanitation required strengthening, it was being weakened and rendered less fitted to cope with this new condition of things. With such surroundings were station hospitals introduced, and the last remaining tie which linked medical officers to regiments was entirely severed." Since 1884 the acquaintance of medical officers with corps and *vice versa* have been of the most passing and fitting nature; and the stay of medical officers in stations has been so short, as to make it very improbable for them to detect sanitary defects and impossible for them to see those defects remedied when discovered. It is far from being uncommon now-a-days for members of the medical staff to do duty but for a few days in a station. It is hard to surmise the principles which regulate transfers and postings of these officers; changes and removals have been the *disorder* of years. For a few days there may be found very frequently a great many more surgeons than the station needs, and this condition is very soon followed by a marked dearth of medical officers. These great and frequent fluctuations in the medical establishments of station hospitals lead of course to distributions and re-distributions of wards and patients with very easily conceivable ill-effects on the sick soldier, who may, in the course of a few days, pass through the hands of two, three or even four medical officers, each one probably going over old ground in the treatment of the case. Medical inspections and sanitation receive scant consideration under these unsettled and ever-varying circumstances; and without going the length of saying, that any particular disease or diseases are the direct outcome of these circumstances, we urge that the health and efficiency of the army in general must suffer therefrom. The station hospital system, moreover, leads to most disastrous computations, as calculations are made from very narrow and limited bases. In the matter of the strength of the different grades of the medical service, these falsely economical calculations from restricted data become strikingly and painfully apparent on the smallest military contingency or crisis. Our military medical requirements have evidently been worked out and based on station hospital needs, on which has been provided a small percentage of a reserve for casualties and war emergencies; and that our strength of medical officers and subordinates has been fixed at dangerously low figures becomes quite plain, when the smallest demand is made for medical men. A fearful struggle to perform almost impossibilities is at once observable; and our small medical force is expected to extend itself over any given area without the efficiency of the army being affected. In the smallest campaign or expedition, the medical service is forced to adopt a regular make-shift

policy, almost dividing one station of its lands to provide insufficient aid in another. The health of both medical officers and subordinates has suffered immeasurably by this make-shift policy, and this policy is in a great measure due to the station hospital system of medical relief to our European army. It may be said that an increase of the medical strength will remedy this evil, which can scarcely be admitted into evidence against the station hospital system; but similar defective calculations in respect to other items and matters may also be detectable if the system were impartially scrutinized; and if those defects were remedied, as they should be, both for the efficiency of the service and for the well-being of the British soldier, it is very doubtful if the station hospital system will still retain its charm of economy, which, as we said at the beginning of this article, is what the authorities appear to have been much smitten with in its adoption. Dr. CLIMO says that as a consequence of the new system "there gradually set in a loosening of that union and sympathy which previously existed between regiments and medical officers. Year by year this estrangement increased, and imperceptibly, but not the less disastrously, it was regimental sanitation that felt this pernicious influence." Any impartial observer and enquirer must subscribe to this opinion; and we hope that all those of the medical staff who are similarly convinced will, directly or indirectly, help towards the re-introduction of the old system by which every regiment was an independent and distinct unit in the matter of its medical provision both in times of peace and of war.

:o:

THE UNHYGIENIC GARB OF THE BRITISH SOLDIER IN INDIA.

THERE no doubt were and are, very plausible reasons for the adoption of the style of dress with which our soldiery in general are attired. We see no reason, however, why the martial garb should not undergo modifications in some respects. Indeed, in seriously considering its disadvantages, we think that it is almost the very ideal dress of discomfort; and it is surprising that, in the changes which have from time to time been made, certain positive defects were not long ago removed. "Tightness and stiffness" appear to have been the two most important considerations with the designers of military uniforms; and tightness of dress and stiffness of bearing are the chief characteristics of a son of Mars. Smartness of attire is what military authorities are particularly solicitous about, but in attaining this object many other desirable and more important considerations are sacrificed. Nobody seeing a British soldier "walking out" will feel that his country's defender is at ease "or at home" in his dress. In fact one's feelings are almost akin to pity in contemplating the straight-jacket-like attire to which Tommy is condemned for each period as he may have enlisted. People of both sexes, and men both in and out of our profession, have fought long and well in endeavouring to effect reformation in the nature and details of feminine fashionable attire, which has been freely denounced as disease-begetting, restrictive or suppressive of natural functions, &c.; while our soldiery are compelled to sin hygienically in the matter of dress in much the same respects. It is hard to imagine why the hooked stand-up collar should have such

enforced general adoption, and have for such a long series of years enjoyed the marked favour which it apparently does in the eyes of the military. One would almost think that the discomfort of the arrangement is a dire necessity, and that it has been impossible for human ingenuity to invent any improvement. A detachment on the march gives ample evidence of the discomfort of being buttoned up well nigh to one's chin, for every soldier takes the earliest opportunity when on the move, of unloosening the grip which his tunic collar has of his throat. However well or easy fitting such collars may have been at the time that they received the master-tailor's attention and care, they are certainly not the most comfortable things of their kind; and with the smallest amount of physical development they become a positive nuisance. Even in the looser and easier fitting "khaki" of the latest pattern, there is a perpetuation of the same evil. With regard to the warm and full dress tunics, the stand-up collar must be voted a painful affliction. Not only is the military collar a source of discomfort, but it is also dangerous. Some years ago, a service medical officer pointed out that heart diseases in the army were probably the result, in many instances, of the military style of collars; and one can easily understand how this prolonged pressure on the carotids may cause cardiac affections. The heart must be excited to work more powerfully than natural, in order to overcome the obstruction that is offered to the circulation at the neck, and valvular insufficiencies, hypertrophies, or aneurisms may result. The remarks made by Dr. PARKES in his "Practical Hygiene" on the English soldier's stiff "stock," apply with almost equal force to the tunic collars now in vogue with the military. He says: "It certainly seems wonderful that an apparatus of this kind should have found defenders; for it was not merely uncomfortable, and somewhat impeded the return of blood through the external jugulars, and hindered the action of some of the accessory muscles of respiration, but also rendered impossible the bending and varying attitudes of the neck which occur when a man makes a strong exertion. For great exertion with the upper extremities cannot be made, if the clavicles and scapula are not rigidly fixed; and they cannot be fixed unless the neck can easily bend. On every account, physiological and mechanical, the neck should be left as bare as possible."

The British soldier is too much tightened up in every other portion of his attire, for tunic and trousers alike are so cut that they exercise general undue pressure. In some corps in particular, this closeness of cut is carried to an absurd extent, and the outer garments are made to fit with such ridiculous exactness to figure, as to almost appear as a moulded encasement. Dress of this kind does not allow of the least ventilation, and must cause a dangerous retention of cutaneous exhalations. With a flannel shirt and a close-fitting tunic buttoned up high, one is practically in a hot-pack, which, however valuable in the just and proper application, must be harmful and exhausting in its protracted and unnecessary employment. The overaction of the skin which is excited by the pack-like nature of his dress must increase the soldier's chances of respiratory diseases and disorders due to sudden chills, on his divesting himself of his tunic

immediately on his return to barracks. Then again, it must be remembered; that the action of the lungs, chest walls, and abdominal muscles are restricted and interfered with by the pressure of these close-cut garments; and here again are further objections on physiological grounds to their sanctioned use and enforced adoption. We will again quote from DR. PARKES to shew what are some of the general principles that should be kept in view in designing a good, rational, and comfortable military dress. "Clothing should afford protection from cold or from warmth, without at all interfering with the freest action of muscles or the circulation of the blood, and without pressing on any important part. A good tunic should have a low collar and be loose round the neck, over the shoulder (so as to allow the deltoid and latissimus the most unrestricted play) and across the chest. Looking not only to the comfort of the soldier, but to the work and force required of him, it is a great mistake to have the tunic otherwise than exceedingly loose. A loose tunic, a blouse in fact, is in reality a more soldier-like dress than the tight garment which every one sees must press upon and hinder the rapid action of muscles. The trousers should be very loose over the hips and knees and gathered in at the ankle, so that merely sufficient opening is left to pass the foot through. The trousers at present are made so tight over the hips that to overcome their resistance some force is lost every time the muscles act."

Considering the soldier's dress in the light of the foregoing remarks, it looks as if the authorities have pledged themselves to determined opposition to hygienic and physiological considerations; for, as we have shewn, the soldier's dress offends against these considerations in every way, and is almost exactly the reverse of what it should be. We do not see what objection there can be to the universal adoption of the turned-down or flap collar used by some arms of the service. It is dressy and comfortable, and should commend itself to any one. The more recently introduced style in which the *khaki* tunics are made, may with every benefit be generally adopted in respect to the white and cold weather tunics. It evidently does not seem desirable to the authorities that medical officers should pronounce officially on the style of a soldier's clothing; for in official reports medical officers are required to state simply whether the clothing of the men has been sufficient and suited to the season of the year. We think that if they were asked to report also whether the clothing is in any particular objectionable on hygienic or physiological grounds, the authorities would, from time to time, be furnished with ideas out of which could be evolved a style of dress more rational in every respect than the present.

AGE AND THE MALIGNANCY OF TUMOURS.

EVERY one must first noticed in the breast after the thirty-eight years epoch is, in the great majority of cases, primarily malignant; in the remainder it is certain, sooner or later, to become associated with malignant features in one form or another. From this sweeping rule, the most simple cyst with in the gland parenchyma, or dilated duct, is not exempt.—*Dr. Herbert Swan.*

COMMENTS AND NEWS.

CIVIL APOTHECARIES AND CIVIL ASSISTANT SURGEONS IN MADRAS.

REFERRING to the intended action of the Indian Medical Association on behalf of Civil Apothecaries, a correspondent writes as follows:—

"About the position, &c., of Civil Apothecaries and Civil Assistant Surgeons. These two grades are quite distinct. The strength of the establishment of Civil Assistant Surgeons stands at one for each district and a small percentage for contingencies. This grade was introduced by Surgeon-General CORNISH in 1888 for the purpose of sharing the heavy work of the district medical and sanitary officers, and in order that the head-quarter station of a district may have a well qualified medical man during the absence of the District Surgeon on tour, &c. During these absences of the District Surgeon, the Civil Assistant Surgeon is literally in medical charge, and does all the duties of the District Surgeon. The distribution of the medical and sanitary work of a district between the District Surgeon and Civil Assistant Surgeon is not specifically defined by regulations, and varies in each district. Medical subordinates attached to Local Fund, Municipal or other hospitals at the head-quarters of the districts are of the Hospital Assistant class. Civil Apothecaries are placed in charge of the larger civil hospitals and dispensaries of taluqs (district sub-divisions). In war and other emergencies, when District Surgeons, who are commissioned officers of the I. M. S., are taken for military duty, the Civil Assistant Surgeons act as District Medical and Sanitary Officers; so that, under these circumstances and inasmuch as Civil Assistant Surgeons may have to inspect outlying hospitals, the Civil Apothecary is officially under and subordinate to the Civil Assistant Surgeon. A Civil Assistant Surgeon is a gazetted officer in official language, a Civil Apothecary is not. A Civil Assistant Surgeon must hold at least the L. M. and S. degree, but Civil Apothecaries need not. Their college course is the same as that of W. M. O's. A Civil Apothecary, and for the matter of that, even a Civil Hospital Assistant, may by selection to a certain percentage of vacancies occurring, be transferred to the Civil Assistant Surgeon establishment. Civil Assistant Surgeons then are posted to districts. Civil Apothecaries to individual hospitals and dispensaries of districts.

The pay of Civil Assistant Surgeons ranges from Rs. 100 to 200 after fourteen years with local allowance of Rs. 50; so that they draw from Rs. 150 to 250 per mensem. The increments are septennial. Civil Apothecaries draw from Rs. 50 to 200 after 30 years' service with charge allowances of Rs. 25 and 50 according to years of service. There are something like 150 Civil Apothecaries on the Madras Establishment, but only about 25 Civil Assistant Surgeons. The position of the Civil Apothecary may be said to be one really and officially subordinate to that of the Civil Assistant Surgeon, only that the latter's work lies almost altogether at head-quarter stations, while that of the former is at outlying taluq hospitals and dispensaries. This subordination is not felt by the Civil Apothecary, and the Civil Assistant Surgeon has not many opportunities of exercising his official superiority.

ARGUMENTS FOR AND AGAINST VIVISECTION.

DR. EDWARD HANINGTON, Senior Moderator in Natural Science, Trinity College, Dublin, in a contribution to the *Statesman*, has been at some pains to demolish the arguments in justification of vivisection adduced by Surgeon-Colonel HARVEY in his address at the Indian Medical Congress. DR. HANINGTON considers firstly DR. HARVEY's statement "that the necessity of experiments is recognised

almost without exception by the medical profession." Dr. HANGHTON contends that if experiments are to be regarded as necessary, they must be generally useful and give reliable results. Dr. VAN VYME of Antwerp has, however, stated that he could not base his opinions on these experiments, while Professor GOURS of Strasbourg, a noted vivisectionist, has said in writing of the functions of the brain that his experiments were of no value for the pathology of the human brain. Again several leaders and teachers of medicine are opposed to vivisection, for instance, Sir CHARLES BELL has said that confusion is one of the results of vivisection, and that experiments on animals have never been the means of discovery. Sir THOMAS WATSON said he had no faith in vivisection experiments; Sir WILLIAM FRASER has come to the conclusion that no surgical operation has been initiated by a similar operation performed on lower animals; Sir JAMES PAGET admitted with JOHN HUNTER the danger of arguing from physiology into practical medicine and surgery. All these disprove the general recognition by the profession of the necessity for vivisection.

Considering in the next place the question of cruelty, and taking "cruel" as meaning "devoid of pity, merciless, savage" as defined in CHAMBER'S etymological dictionary, Dr. HANGHTON states that in the appendix to the report of the Royal Commission on vivisection, appointed in 1875, it is shown that dogs were baked alive, boiled alive, and partially flayed alive; that dogs' skulls were bored and corrosive acids injected through the holes, &c. Dr. SCHAFER admits that he never gives anaesthetics to frogs or renders them insensible; and Dr. KLEIN says that he pays no regard at all to the sufferings of the animals. Dr. SCHIFF of Geneva finds it necessary when dogs come into his laboratory, to cut out two of their nerves—the nerves of vocalization, to prevent the inhabitants about being disturbed by their howls during experiments being conducted. CLAUDE BERNARD, a prominent vivisectionist, compares the sufferings of the animals to the tortures of the damned; and MONTAGAZZA endeavoured to produce the greatest amount of pain which the animal could endure while alive.

Dr. HANGHTON objects to the sale and administration to human beings of such alleged antidotes as KOCH'S lymph for tubercular disease, Dr. DOMINGOS FREIRE'S stuff for yellow fever, Dr. FERBAN'S cholera virus, HAFKINE'S inoculation, BEBBING'S antitoxin, &c. He regards all these as poisons, and says that the burning question now in England is "whether we are to be poisoned when we are sick, whether a clean thing can be brought out of an unclean, and whether health is to be best promoted by the erection of poison manufactories or by the well-tried methods of hygiene." With regard to the supposed gains by cerebral localization obtained by these experiments, Dr. HANGHTON says that Dr. CLARKE, considering the statistics of operations and the impossibility of localising most tumours of a kind that ought to be removed, said that "he would rather keep such a tumour (were he the subject of it) than allow his brains to be exploited in the interest of science."

AN EDITOR'S HINTS TO CONTRIBUTORS.

THE Editor of the *Medical News* appears to have had rather a harrowing experience; so much so, that he has found it very necessary in a three-page article to ask his contributors to mind the error of their ways, and to lay down some instructions for their guidance. In the matter of articles sent for publication there is, no doubt, a great deal to cause the Editor of any journal much vexatiousness of spirit, and one must be a little more than human if he does not feel disposed to swear a bit at times.

We heartily sympathise with our contemporary. His experiences of these evil incidents in writing have been an

commonly great and trying. Denouncing the way in which writers have of sending the same articles, or very similar articles, to several journals, our contemporary says: "Do not hesitate to characterise such a proceeding in *damning and plain English*; it is certainly *exemplary* in the extreme. It may be due to gross stupidity, or to flagrant trickery." If contributors can be got to abide by our contemporary's suggestions, a great boon will be conferred on editors in general. These suggestions are: "think well before you write, and have something of value to set forth; put what you have to say succinctly and clearly; do not report *clumsily*, using meaningless scraps and fragments of sentences; pay attention to the proper use of compound words, hyphens, and punctuation marks, &c., avoid 'high falutin' and write as you would speak; be modern and crisp, and do not cling to antiquated usages; write legibly and spell correctly; use good paper and leave a full inch of a margin; let not the lines be too closely written; write on one side only of the paper; do not fold the paper more than twice. Will contributors extend some sympathy to editors exposed to irritation and annoyance from so many sources; and will they give these suggestions their kind and merciful consideration?"

NURSES AND THEIR PROFESSION.

WE gladly condense the opening address delivered by Dr. P. S. DONNELLAN at the Training School for Nurses, Medico-Chirurgical Hospital, Philadelphia, and we hope that those who follow the profession of nursing will lay to heart the excellent advice given them in that address. Dr. DONNELLAN spoke of nursing as one of the noblest occupations of womankind. Every woman, he said, is a nurse, she having at one time or another of her life had charge of some body else, a child or an invalid. History teems with accounts of the heroism, self-sacrifice, and devotion of those noble women, the Sisters of Mercy and of Charity, who for the Glory of God and the honor of their sex, faced death itself in the discharge of their duty. Time was when nursing in Europe and America was a disgrace; and self-made nurses of the SARAH GAMP type were not fictitious beings. Trained nursing has, however, become a medical necessity, and without integrity in nursing the most eminent professional skill is unavailing. The qualities essential in making a good nurse are:—a distinct liking for one's calling; good health, as nursing duties are exhausting to mind and body; personal neatness; good sight and hearing; a good common-school education; and a cheerful disposition. A nurse should never be in a hurry, as bustle and confusion make a patient nervous; she should avoid whispered conversation, as this arouses a patient's suspicion unnecessarily; she should carry out the directions of the doctor to the very letter, never disclosing his motives or methods; she should remember that her duty is to observe facts and not to form opinions; and that "a first-rate nurse only makes a fourth-rate doctor." She should not trust to her memory, but should put down in writing all instructions received, and whatever she may notice or have to report at the physician's next visit. She must not be above doing a certain amount of menial work. Her attitude towards the physician should be characterised by deference and by courtesy, avoiding the extremes of familiarity and servility.

A PUBLIC PROSECUTOR MAKING MISTAKES.

IN a case recently tried before Mr. J. D. ELLY, Police Magistrate of Sankish, the *Prosecutor* made a report, an extract from which runs as follows:—

"*Magistrate*.—Mr. GASTLEY, a friend of Mr. CHERRY, says that this morning he and Mr. CHERRY walked, at about 10 o'clock, to this court; but on the road, Mr. CHERRY was taken ill

and the absence of Dr. WALLACE for medical aid. Dr. WALLACE, after examining him, had certified that he was unable to attend court.

The Public Prosecutor, Babu ANURUPAN SEN, said that as Dr. Wallace was not a Presidency Surgeon, he would require Mr. Gaitley to make sure if Mr. Croft were ill or not.

Mr. GEORGE OAKLEY, on being examined, said that Mr. Croft was suffering severely from gout, and was bed-ridden.

The case was adjourned till the 4th proximo.

The station is ours. We refer to the falsified words emphatically as emphasising a most illegal and unwarrantable act on the part of the Public Prosecutor in this case, which will be brought to the immediate notice of His Honor the Lieutenant-Governor of Bengal. It is perfectly correct that the Government enacts that medical certificates granted to its own servants shall, before they are officially accepted be either signed or countersigned by a Presidency Surgeon. Nowhere, however, in its Rules or Regulations does the Government enact that in Courts of Law certificates shall not be accepted when signed by qualified medical men other than Presidency Surgeons. Such a law would be a most arbitrary and unwarrantable infringement not only of the rights and privileges of independent physicians outside the service of Government, but it would be an unjust interference with the liberty of private persons in the most important and delicate concerns of their daily life. We protest most emphatically against the action of the Public Prosecutor in this case, and have no hesitation in denouncing his conduct as a serious breach of professional etiquette and a dereliction of duty that demands censure at the hands of Government.

NO CHLOROFORM FATALITIES IN INDIA.

As we open our British mail exchanges week after week, we find the ominous heading "MORE CHLOROFORM FATALITIES" in almost every issue of our contemporaries. To physicians and surgeons practising in India, this kind of experience looks very much like "culpable homicide not amounting to murder." For why should surgeons in England "kill" their patients with chloroform while surgeons in India have no fatalities? Surely grave errors in the methods of chloroform administration by surgeons in England. What then is the error? Can it be that a tropical atmosphere or the influence of a tropical climate engenders an immunity to chloroform disasters, for we have no disasters either among European or Indian subjects in India. This can hardly be the case, as immunity from fatality is the invariable experience of chloroform administrations in our *All stations*, where the climate and atmospheric changes are similar to those of Western temperate regions. We are strongly of opinion that an imperfect knowledge of practical chloroformisation is the root of the evil. Throughout India, STRYKE'S method is adopted generally, and it is to the universal acceptance of the principle of this method that protects India from the terrible experience met with in every-day English surgical practice. It is useless to hang upon theories as to "heart failure" and the need for "pulse watching" when such a nightmare of a theory is pregnant with fatal results. Surely the immunity from disaster which attends the practical application of Stryke's method of chloroformisation, should stagger those who cannot realize such immunity from other methods, forcing them into the belief that the continuance of a practice of chloroformisation that is notoriously dangerous and often fatal, is enough to justify an investigation that such conduct is not only imprudent but criminal.

HOW CALCUTTA LIVES.

DURING December last the natural food supply of Calcutta consisted of 8,225 bullocks, 1,366 cows, 4,579 sheep, 1,874 goats and 874 kids, making a total of 30,915 animals slaughtered. Of these, 916 lbs. of meat were condemned and destroyed as being unfit for human food. The other kinds of food confiscated and destroyed consisted of fish, vegetables and fruits, potatoes, grain, sweets, and milk products. From the 125 dispensaries inspected throughout the town only 3 drs. of drugs were confiscated. There were 184 inoculations for cholera performed, only 1 person being a European. In one house 8 members of a family of 9 had been inoculated in March 1903. Cholera broke out in December, with the result that all were decapitated, while one of the 6 non-inoculated members was attacked and died next day. The ratio of male births to female in all Calcutta was as 112:100, while that of male deaths to female was as 136:100 for December last. The ratio of *Christian* births is *twice* was 30.5 *per mille*; of deaths, the largest number occurred between the ages of 20 and 39, (514) and the smallest, between 5 and 9 years (81); of these the ratio per 1,000 was: Christians, 25.2, Hindus, 41.4, Mahomedans, 39.7, and other classes, 45.8.

PROFESSIONAL ADVANCEMENT.

THE *Journal of the American Medical Association* points out that to a large extent a man's standing in his community is "measured by the general standing of his profession; and that of the obligations which a man takes upon himself when he enters a profession. One of the most important is the general advancement of the profession and of its members." This advancement, however, can be best, if not only, effected by a powerful association, having a powerful journal. We commend these remarks to all our readers, and hope that they will see that for their individual interests and the good of their profession it behoves them to help in the growth, development and expansion of our association and its journal by bringing fresh additions into union with us.

THE EFFECT OF A DREAM.

LOVERS of the marvellous have the opportunity of finding a strange coincidence in a story recently told at the coroner's court here. A girl, aged thirteen disappeared from her home; her disposition was taciturn and sulky, which, coupled with her expressed apprehension of water, led to the worst fears being entertained by her parents. Her body was subsequently found in the canal. The aunt of the deceased, hearing that the girl was missing, dreamt that she (the aunt) was walking along the bank of the canal, and while looking into the water saw the face of her niece. The police were asked to drag the canal at the spot indicated in the dream; they did so, and at once found the body. Such was the simple story told at the inquest, a statement which if made in a novel would be ascribed to the powers of the writer's imagination.

PUBLIC LAUNDRIES.

SAYS *Indian Engineering*—We are pleased to observe that the methods and materials employed in the washing of clothes in Calcutta are no longer to be left to the tender mercy of the *dhobi*, unregulated and unsupervised. The proposal inaugurated at a recent municipal meeting that *dhobis* should be established about the town is a commendable one, aiming straight at remedying an evil which recent events have brought into daylight. It is to be hoped that this practical and urgent requirement of a large city will not receive that scant consideration which is the common fate of measures that are the most useful and the most likely to lead to improved public health conditions.

OPIUM SUICIDES.

DR. GREG writes an account of his medical missionary labors in the *Ethiopian*, *Record* and cites one or two interesting cases of suicide by taking opium. The first is that of a woman set. 46, who lost one son by opium, and her only surviving son died suddenly, whereupon she poisoned herself with the drug and sat by the side of her son's dead body near a Buddhist temple to die. Her little daughter remonstrating with her and pleading with her to open her eyes. By means of the stomach pump and strong stimulants to her nostrils, Dr. GREG restored her to life after a hard struggle and much pleading with her friends to be allowed to do so. The second case is that of a young man set. 20, who was stretched out on a mat at the door of a hut situated on the banks of the River *Sangari*, then frozen. He was brought out into an out-house after a long parley and there restored to life. The facility with which opium is obtainable, and suicide being pleasant and painless under its influence, are two factors that bulk largely in causing such frequent suicides by that drug.

A LINK WITH THE PAST.

IN MR. WILLIAM HUNTER BAILLIE, who has just passed away, set. 97 years, we have lost a link with some of the most eminent physicians, anatomists and pathologists of the closing of last century. MR. BAILLIE was the only son of DR. MATTHEW BAILLIE, who was a physician to GEORGE III, and a celebrated physician too, as well as a scientist. His constitution (which was not robust) was ruined by a large practice, which overtaxed his energies (16 hours a day being devoted to seeing patients). He died set. 62, of phthisis, but his sisters AGNES and—JOANNA BAILLIE (dramatist and poet)—lived to 101 and 88 years respectively. MR. WILLIAM HUNTER BAILLIE is named after WILLIAM HUNTER, the celebrated JOHN HUNTER's elder brother—his mother being SOPHIA, daughter of DR. DEMNAN, father to the Lord Chief Justice. MR. BAILLIE was a barrister and led a quiet uneventful life.

ABNORMAL HOT WEATHER IN CALCUTTA.

THE heat in Calcutta during the past fortnight has been abnormally great and excessively trying. On the 19th and 20th May, the thermometer registered 105° in the verandah, 98° in the shade, and 113° in the open air. Numerous deaths have occurred from heat apoplexy, while the course of many simple febrile disorders has been rendered disastrous and fatal by the oppressive atmospheric temperature. Horses have suffered severely, and many have died from apoplexy and heatstroke. The ice supply of Calcutta has proved lamentably insufficient, hence an article that is not a luxury but a necessity, has been placed beyond the reach of the poor, who cannot buy it owing to the high prices now charged for ice.

JAWBREAKING COMPOUNDS.

MUCH as the profession has been growing accustomed to the thundering names given to the more recent synthetic and other remedies and compounds, one may pardonably be a little staggered at the name DIMETHYLKETOHexamethane. This formed the subject of a paper read by DR. STANLEY KIPPING at a meeting of the London Chemical Society in March last. The French, however, are not to be beaten in the matter of pharmacopoeial nomenclature; for among other things they can boast of the "acide anhydrosulfamide-benzolique."

HOW CHOLERA MAY BE STAMPED OUT.

SURGEON-MAJOR HAWWOOD, F.M.S., writes to a local contemporary:—"A paragraph has appeared stating that cholera of a virulent type has broken out in cantonments in Dura-Dura. I have much pleasure in stating to you that we

have not had a single case of cholera at Dura-Dura cantonments since 14th August 1894, on which date the new water-supply from filtering beds at Puka was distributed by stand pipes in the cantonment bazaars and cantonments."

BLACKMAILING.

THE Wabech borough magistrates have had before them a charge against MR. GEORGE BURY of Wabech, house surgeon of the cottage hospital, of assaulting one FANNY MAUD LILLIAN JOHNSON. The examination was very damaging to the complainant, and the case was dismissed after a very brief consultation. MR. BURY is to be congratulated, not on the dismissal of the case, which never assumed a serious aspect as far as he was concerned, but on the manly way in which he met the charge. A medical man deserves the thanks of the profession and of all respectable people for exposing such a case.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

We have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue:—

- O. F. Peter Sebastian, Civil Apothecary, M.M.A., Jag-gayapet, Kistna Dist.
- Maung Thein Maung, Hospital Asst., Central Jail Hosp., Rangoon.
- B. V. Narsimangar, Hosp. Asst., Jagalur, Chittaldroog Dist.
- M. Lakshmana Rao, Hosp. Asst., Chellakere, Chittaldroog Dist.
- V. J. Packianathan Nadhar, Hosp. Asst., Hijiyr, Chittaldroog Dist.
- S. Gopalsamy Chetty, Hosp. Asst., Hosadurga, Chittaldroog Dist.
- M. S. Maria Pillay, C.M.S., Molakmuru, Chittaldroog Dist.
- N. Narasimya, Hosp. Asst., Holakere, Chittaldroog Dist.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

SHORT ITEMS.

Dr. Ernest Hart thus charges the Indian Medical Department:—"The official regulations with regard to the prevention of cholera among soldiers are misleading and medieval in their ignorance, and the rules ought to be re-written from beginning to end by some one who understands the elements of the subject."

Surgeon-Major Sir James R. A. Clark, who has retired from the army, was born in 1852, and succeeded his father, the late Sir Andrew Clark, as second baronet in 1893.

The Civil Surgeon of Mysore has called the attention of the Municipality to the immediate necessity for the erection of a suitable building for the exclusive purposes of post-mortem examinations.

Government have ruled that medical pupils of the Agra Medical School are entitled to free quarters or compensation while attached to hospitals, pending their rank as sub-hospital assistants.

In future, Military Medical Officers in permanent civil employ will not be eligible for rewards for posting in large-ages under military rules.

Mrs. B. N. D. Bhargava, and S. B. Bhargava of Bombay
were present at the Primary Examination of the Society of
Scientists of London.

Current Medical Literature.

MEDICINE.

Puerperal Polyn neuritis.

DR. LUNZ of Warsaw has recorded in a recent number of the *Deutsche Medizinische Wochenschrift* an interesting case of this rare and peculiar condition, in which the symptoms differed considerably from those usually recognised. In the usual form there is an isolated neuritis of the upper or lower extremities, while the case here mentioned resembles more closely post-diphtheritic paralysis, inasmuch as difficulty in swallowing and diplopia were present, and also what is rare in diphtheritic paralysis, an affection of the face. With regard to the etiology of the condition, it does not seem to follow only a pathological puerperium. DR. LUNZ believes that cases can be divided into three groups: a pyrenic or septic group, in which the neuritis follows some local infection; a cachectic form, which succeeds grave disturbance of nutrition, such as may be produced by loss of blood, persistent vomiting, &c.; and a third group, in which neither infection nor cachexia can be regarded as the cause, but in which the psychological disturbances which the confinement produces is to be regarded as determining the onset, just as it probably does of the puerperal psychoses which occur without puerperal infection. He urges in conclusion, that obstetricians and psychologists should co-operate to elucidate the obscurities of these important and little understood conditions. —*Lancet*.

Sulphonal Poisoning: Recovery.

BURGEON-CAPTAIN C. BIRT, Army Medical Staff, Bombay, reports in the *B.M.J.*—W. G., aged 14, weighing 28 kilograms, took from 5 to 6 grammes of sulphonal in the form of tablets, which he mistook for harmless lozenges. Two hours later his stomach was artificially emptied. He was then very drowsy, and shortly afterwards fell into a deep sleep, from which, however, he could be partially roused. He remained in a semi-comatose state for twenty-four hours. When he had so far recovered as to be able to answer questions, he complained of headache, insomnia, extreme giddiness, and sleepiness. Two days passed before he could stand. When he attempted to walk he staggered and fell. His attitude and look bore a striking resemblance to the effects of alcoholic intoxication. Giddiness, somnolence, and muscular inco-ordination continued for a week after taking the tablets. The last sign of danger was inability to walk in the dark. His urine was increased in quantity, and was highly specific gravity (1020 to 1025). It contained no albumin, sugar, or albumin of formed elements. The examination of his blood was found to show nothing, as in health. There was no diarrhoea, but the symptoms to

remain separate, as E. SCHAEFER has observed in instances of chronic poisoning with this hypnotic. Constipation was the only disorder noticed in his digestive system. The temperature and pulse remained unaffected."

Alterations of the Urine in Malaria.

FOR LAMBECK related the results of researches which he had made in two cases of malaria. In these cases the elimination of nitrogen was in relation with the elevation of temperature; the proportion of urea and the total quantity of nitrogen were not modified; the elimination of ammonia also was in direct relation to the elevation of temperature; the quantity of urea was augmented, but the relation between the ammonia and the total quantity of nitrogen was normal. During the febrile accession the quantity of phosphates was found diminished; they did not increase until after the access. FREUND had also found a retention of phosphates during the febrile stage in some other infectious diseases.

The elimination of chlorides, contrary to what occurs in other infectious diseases, is enormously increased during the malarial paroxysms; this fact is so characteristic, that the author thinks it may be accorded a real diagnostic value—*Jour. Amer. Med. Assoc.*

**Hereditary Syphilis with Acute Nephritis
in Infancy.**

DR. HOCK reports the case of a child born at term, the mother being a II para who had contracted syphilis during her first pregnancy, and had been delivered in the eighth month of a child which died shortly after. The second infant showed at birth no symptom of the disease, except coryza. At the age of eight weeks he was attacked by erythema, which soon disappeared under the influence of protiodide of mercury, but within three days an edema of the pelvis developed. An examination of the urine showed albumin and numerous casts, as well as red and white globules. Other symptoms of syphilis now appeared, but were controlled by iodide of potassium.

This is the first instance of nephritis occurring so soon after birth.—*Univ. Med. Jour.*

Rhythmic Cough of Nasal Origin.

JOUROUKACHI has reported the case of a woman who came under observation on account of persistent cough, which has been present for five-and-a-half years. At first occurring at considerable intervals, the attacks gradually recurred with greater and greater frequency, every four or five minutes, and causing great fatigue. The cough somewhat resembled the barking of a dog. In the absence of a discoverable lesion a diagnosis of hysteria was made, but, despite all treatment, improvement was not effected. The patient coming under observation a second time, a tumor, which proved to be a lymphadenomæ, 1 inch long and $\frac{3}{4}$ inch thick, was discovered in the naso-pharyngeal space in contact with the vomer. On removal of the neoplasm the cough permanently disappeared. — *Medicine Moderna*.

Management of Mice.

The danger in measles and whooping-cough lies in the complications, e.g., bronchitis and pneumonia, which may be coincident with the eruption on the skin and on the mucous surface of the bronchi and pulmonary vesicles—broncho-pneumonia secondary upon measles or whooping-cough will come either from lack of judicious treatment, or from the complications of the patient. Treatment should consist in keeping the patient in a warm room, and administering repeated full doses of acetate of ammonia, which is stipulated by the laws and destroys the infection—*Compt. in Jour. de Med. de Paris.*

Pro-Tuberculous Albuminuria.

TERRANCE cited a number of cases that led him to believe that some cases of tuberculosis were preceded by the development of albuminuria. The most striking features of this condition observed were its intermittence, with irregularity of recurrence, its occurring most commonly in the morning, and its association with phosphaturia. It alternated with attacks of catarrhal bronchitis or congestive phenomena of varied kind, disappearing with the development of the pulmonary disease. The condition is attributed to renal congestion of toxic origin from the action of the products of the tubercle bacillus.—*Med. News.*

SURGERY.

Ophthalmology in Bengal and Madras.

BRIGADE-SURGEON LIEUTENANT-COLONEL E. F. DRAKE-BROOKMAN, F.R.C.S., I. M. S. (retired), writes to the *British Medical Journal* :—

"I have read with interest the abstract "Of the retrospect of Ophthalmology" read by DR. LAL MADHUB MOOKERJEE, Teacher of Ophthalmology in the Calcutta Medical School, at the recent Indian Medical Congress, and reported in the *British Medical Journal* of 26th January. Without wishing to detract in any way from the honor claimed for the Bengal Presidency as the pioneer in this direction, I wish to state that the so-styled "benighted Presidency"—Madras—should not be lost sight of as having, at an earlier date than that mentioned by DR. LAL MADHUB MOOKERJEE, taken the lead in treating those suffering from diseases of the eye, in regularly appointed hospitals.

In the *Review of the Eye Infirmary, Madras, for the five years ending March 31st, 1882*, drawn up by me at the wish of the Surgeon-General with the Madras Government, I have stated (my information having been obtained from old records in that institution) that :

The eye infirmary was originally founded in July, 1819, by the Honourable Board of Directors in a house known by the name of Compton's Gardens, in the district of Royapettah, under the superintendence of Surgeon R. RICHARDSON. In the June of the following year (1820), for certain reasons, of which there is no record, the present locality (Egmore) was selected; and the former building having been vacated, the hospital was reopened in the premises at present occupied for the purpose, Surgeon RICHARDSON continuing to hold the superintendence of it. The reports submitted to the Board of Directors from time to time, of the working of the hospital, appear to have been of so favorable a character as to induce that body of gentlemen to continue to maintain the hospital; and in order that a suitable successor might be found in the possible absence of the surgeon at any time, Assistant-Surgeon T. M. LANE was appointed as an assistant to this officer in October, 1823.

Further on DR. LAL MADHUB MOOKERJEE says : "For the last thirty years nearly 300 operations have been performed yearly in the Eye Hospital, Medical College." For want of sufficient data, I am unable to give statistics of the operations performed at the sister hospital at Madras for so long a period; but the following figures will be interesting in shewing that for nearly eleven years, ending December 31st, 1891, equally good work has been done at the latter institution.

In my second *Review of the Ophthalmic Hospital, Madras from April 1st, 1851, to December 31st, 1881*, submitted to the Madras Government, I give the yearly figures, which show a total of 12,526 for the eleven years, an average of 1,139 for each year.

If DR. LAL MADHUB MOOKERJEE'S "nearly 300 operations" refer only to cataract extractions of kinds as one

might infer from the context, I would mention that, out of the total of 12,526 operations, 5,533 were performed for removal of cataracts during the eleven years above named, at the Ophthalmic Hospital, Madras.

While dealing with the subject of medical work in Madras, it may not be out of place to mention here two other directions in which Madras has taken a prominent, if not the leading, part: I refer first to female medical education, and second, to the institution of a Chair of Dental Surgery at the Madras Medical College, the appointment of Mr. H. J. GOULD (since retired and now in practice in London), as the first Professor of that subject.

The Surgical effect of Rifle Bullets.

DR. CHRISTIE recounts his experiences among the wounded Chinese in the present war in the East, in the *British Medical Journal*, and emphasizes the differential features of injuries produced by the older large-bore bullets on one hand, and those produced by the modern small-calibre rifles on the other. The rifle in present use in the Japanese army has a calibre of 0.315 of an inch, and projects a copper and nickel-coated bullet, weighing 288 grains, and having a velocity of 1,850 feet per second. Bullets of even smaller calibre than this, *viz.*, of only 0.198 of an inch have produced in the hands of KONKA and HEBLEN better results. The older form of bullets were larger, softer, and of comparatively slow velocity, and produced wounds with which all army surgeons are familiar, *viz.*, the wound of entrance consisted of a broad zone of dead tissue, there was great laceration and splintering of bones in the canal, great explosive action, little hemorrhage, and the exit wound was gaping widely and much torn. The new (mantled) hard bullets of small calibre, high velocity and deep penetration, produced clean-cut wounds, slightly lacerated, with little splintering of bone and less explosive action. But they are prone to bleed readily. Being clean-cut, small, and aseptic, they heal perfectly and rapidly.

At long ranges, towards the end of their flight, these small-calibre bullets are apt to *somersault*, and by striking sideways, often produce much splintering and comminution of bone. *Ricochet* hits often tend to separate the outer shell of copper and nickel and the remaining hollow leaden core being soft, produces very much lacerated wounds, being converted, in fact into the old form of bullet. Wounds of intestines producing minute perforations, offer good results when followed by expeditious laparotomy. Lung wounds also give better results than formerly. The areas of the zones of fire are increased by the use of these small-calibre weapons and render "first aid" in the field very risky from the casualties likely to happen to the personnel of the medical staff, as has been abundantly demonstrated in the late war.

The Treatment of Traumatic Peripheral Neuritis.

M. DELORME presents the following treatment for neuritis: The clatrix is seized between the thumb and forefinger and pressed with great force for several seconds; an interval of a few minutes is then allowed to pass, and the pressure is again applied. Generally one application is sufficient; but in obstinate cases the pressure has to be applied two or three times at intervals of from three to four days.

The results obtained from the application of a method so simple and so easy are said to be excellent. M. DELORME cited eight cases which had come under his observation in which there had been complete recovery.—*Précis Médical.*

Auto-Inoculation of Hard Chancre.

S. NOLIN reports three cases of this kind. In the first the seat of the chancre was on the inner side of the eyelid, which the patient had rubbed continually, a particle of pus having lodged in the conjunctival *sul-de-sac*. In the second case the chancre was inoculated in the right ear-pix, while in the third it occurred in the folds of the prepuce.—*Brit. Med. Jour.*

GYNECOTRIS AND GYNECOLOGY.**The remote effects of the removal of the Uterus and Ovaries.**

Dr. E. W. CUSHING of Boston contributes an article in the *Boston Medical and Surgical Journal* on the above subject, and begins by asserting that where excision of the uterus for fibroids was formerly attended with a mortality of 80 per cent, it is now less than 20 per cent, and the best results give not more than 6 to 10 per cent.

Again, formerly it was considered bold and dangerous surgery to remove the uterus for myomata, but the operation is now as well established as is that of ovariectomy. The consequence of leaving the myomata to grow unchecked is, a train of pressure symptoms on ureters, intestines, &c., together with inflammations and degenerations in the tubes and ovaries. Small fibroids can now be removed so successfully and safely by the operation of vaginal hysterectomy, that it is good surgery to excise them in all cases, and thus prevent any recurrence.

The remote bad effects of *excision uteri* are said to be: insanity, obesity and the loss of sexual desire. Insanity has been known to follow excision in rare cases, but Dr. CUSHING doubts whether sexual desire is totally lost.

Removal of ovaries and tubes is done for suppurative inflammations, chills, &c., where the symptoms are very urgent and death imminent, irrespective of the remote effects, as the patient must be got out of immediate danger.

They are also removed for *cirrhosis*, which produces persistent dysmenorrhœa and at times pus, &c., also for *varicocèle* of the pampiniform plexus, for *epilepsy* and *hystero-epilepsy* occurring during the catamenia, for *insanity*, and lastly for *nyctomania* and *maturation*.

Removal of the appendages is called for to bring on artificial menopause: all the characteristic symptoms, such as flushing, &c., are present. At the same time their removal is very apt to be attended with atrophy of the vagina and genitals in some cases, and also of sexual desire in others, though this is fortunately a very rare occurrence.

Septicæmia following Parturition or Miscarriage.

Dr. D. ROSE advocates in the *New York Medical Journal* a plan of treatment which he has found highly successful and one which he believes to be original.

The patient is drawn to the bed-edge, a bivalve speculum introduced *per vaginam*, and the interior of the uterus thoroughly swabbed out with borated cotton in a long dressing forceps, until the cotton comes away quite clean and odorless. After this, some clean cotton is dipped into a solution of IODIZED PHENOL and the whole interior of the womb completely drenched with it. As a rule, this first application suffices, but if necessary, it may be repeated next day. It causes no pain nor the slightest unpleasant symptoms, and "the rapidity with which involution takes place, is simply marvellous." Cotton is used in preference to the douche, as it will wipe away septic shields which the intra-uterine douche would leave behind; there is again no danger of fluid entering the Fallopian tubes; and further, the accoucheur can accurately tell when the uterus is sweet and aseptic by the odour and appearance of what he gets away, which cannot be done when water is used. This method also obviates many an operation for the repair of old lacerations of the cervix.

Modified Ovariectomy.

Dr. PERRI, at the Hôpital Broca, has modified his ovariectomy for the past two years by only removing the organs when totally diseased. When laparotomy is performed and the ovary drawn out of the abdominal wound, if it is found partly healthy, Dr. PERRI amputates the affected portion, cauterizes

the stump, and sews the end with silk. In cases with small cysts he opens them by touching with a PAQUERLIN's caustery. In one case, in which he operated upon both ovaries, the patient has since borne a child.—*M. T. & Hosp. Gazette.*

Artificial Fecundation.

In discussions on artificial fecundation, the fact is not mentioned that JOHN HUNTER was the first to perform this. He was consulted by a person who expressed great anxiety to have children, but whose urethra opened into the perineum. HUNTER recommended him to inject by syringe, previously warmed, the semen into the vagina, *post coitum*, during the orgasm. In this connection, it is of interest to remember that AVERROES reported a case of a woman "that conceived in a bath, by attracting the sperm of a man admitted to bathe near her." The most striking feature about this last case is its having been admitted by Mohammedan jurists as a precedent.—*Med. Standard.*

Induction of Premature Labor by the Use of Glycerin Bougies.

THEILHABER contributes a description of a method of using glycerin bougies for the induction of premature labor. For two years past PELZER's method of inducing labor by injection of sterilized glycerin between the membranes and the uterine wall has been well known. While it is usually effective in inducing uterine contractions, dangerous results, such as chill, fever, violent vomiting, and evidences of interstitial nephritis or hepatitis are also reported. These seem due to the chemical irritation of the glycerin on the uterine wall, and to its absorption rather than to any osmotic action it may set up between the fluids of the ovum and itself. The hypodermatic injection of glycerin causes hemoglobinuria and interstitial nephritis. The simplest and least hurtful method of applying glycerin to the intra-uterine surface is that of glycerin bougies. These consist of a rounded thin bougie of fish bone, covered with a thin layer of 1 per cent of sublimate collodion. Over this is a mixture of 5-9 per cent. glycerin and gelatin, which, to prevent moulding, is mixed with 2 per cent. tricresol. The bougies are packed in waxed paper that is smeared inside with 3 per cent tricresol vaseline. Besides these, a second sort are prepared which contain as a nucleus a fifteen centimetre fish bone, and are coated with a 7-8 grammes of glycerin and gelatin. One case is narrated of the use of these bougies by the author with excellent results, two bougies being used. How much influence the mere presence of the bougies had upon the case is uncertain, but it is believed that the glycerin greatly hastened the desired result. The small amount of glycerin used could scarcely be productive of danger.—*American Journal of the Medical Sciences.*

Puerperal Eclampsia and its Treatment.

FERRE PAU relates two cases of eclampsia, both of which were treated successfully by hypodermic injections of an 8 per cent. solution of common salt in distilled water. From 200 to 700 grammes were injected at a time by means of DIEULAFOY's apparatus. FERRE observes that "PERRAZ believes that the introduction of a great quantity of saline water increases blood tension, and, in this way, leads to re-establishment of renal secretion," but he himself is inclined to think that the diminution of renal secretion is the result of the eclamptic seizures, and that the introduction of large quantities of water acts as a nervine sedative by diluting the toxic matters in the blood and thus diminishing their power. The suspension of the attacks allows the circulation to recover its balance, and the secretions become re-established; thus, as in FERRE's two cases, the periods of convulsions or partial suppression are succeeded by those of polyuria.—*Med. Chronicle.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Glycosuria in Healthy Subjects.

LISCOMB AND ROGERS found after giving cane sugar to 17 patients (healthy subjects) —

1. *Saccharuria* occurred in all, the dose varying between 50 and 150 grammes. (2). A large excretion of saccharose is always associated with a slight glycosuria. (3). In some cases the smallest dose causing saccharosuria also caused glycosuria to a large extent (88 per cent). Saccharose appears most readily in the urine, then glucose, and then lactose. The fact that in some cases (16 per cent), the smallest dose (100 grammes) of saccharose caused glycosuria to a large extent, proves that we cannot regard glycosuria as a grave lesion of the hepatic cells. — *B. M. J.*

Pathology of Thomsen's Disease.

THIS disease bears a kinship to pseudo-hypertrophic paralysis, and is called after its discoverer's name, but has also been studied by ERB, who termed it "myotonia congenita." The main features of this disease are: increased volume of muscular masses, accompanied by impairment of power; whenever the affected muscles contract they assume a state of tonic spasm. There is increased excitability to faradism and galvanism, and the "reaction of degeneration" is present. The disease is hereditary. DUB. DEJERINE and SOTTAS publish an account of the morbid anatomy as gathered from a patient *et. 32* who came under their observation and had had the disease from infancy (dying 5 years later from acute nephritis). The muscles of the lower extremities and trunk (those used most) were hypertrophied, and when they contracted they became rigid, relaxing again but slowly. Microscopically there is a nuclear overgrowth: the sarcois substance becomes swollen, the fibrillae fused together, and the strie are retained, becoming more prominent than in health. The diameter of the muscular fibres is increased, also the inter-fibrillar protoplasm. In more advanced stages the sarcois substance disintegrates and vacuoles are found between the fibres. There is no hyperplasia of connective tissue, nor any increase of adipose tissue, as in pseudo-hypertrophic paralysis.

Changes in the Blood in Yellow Fever.

DR. JOSEPH JONES of New Orleans notices this subject. The blood undergoes profound changes during the febrile stage, as is evidenced by the livid purplish jaundiced hue of the skin, along with blisters and passive hæmorrhages from slight abrasions and bleeding from the ears, nose, mouth, eyes, gums and gastro-intestinal mucous membranes. DR. JONES thus enumerates the various blood-changes:—(1). The albumen transudes through the excreting structures of the kidneys. (2). The fibrinous element in the blood is so altered that it clots imperfectly, owing to absence of fibrine due to the action of the febrile poison. (3). The red cells are only slightly diminished, but present a peculiar appearance under the microscope. (4). Extractive matters of blood are increased. (5). Also fatty matters. (6). Accumulation of bile in the blood. (7). Accumulation of the urea, phosphoric and sulphuric acid, chloride of sodium and ammon. carb. of the urine. (8). Rapid dissolution of red blood cells when blood is abstracted from the body. (9). Rapid putrefaction of blood when abstracted from living body or from large vessels *post-mortem*. — *Lancet*.

Pathological Identity of the various forms of Acute Septic Inflammations of the Throat.

A DISCUSSION on the above subject was held in which DR. ERIC SIMON contributed a paper. He sought to identify the following acute inflammations of the throat and neck as being different degrees of violence of one and the same disease; viz. of acute oedema of the larynx, catarrhus laryngitis, erysipelas of pharynx and larynx, phlegmon

of pharynx, and laryngeal angina. He sought the reasons for the doing, in spite of absence of any bacteriological evidence. He said that the question of their primary localization and subsequent development depended probably on the pathogenic germs gaining an entrance through accidental breaches in the protecting membranes. That great difficulty existed in registering cases (according to the present terminology), which passed from atrophic inflammation into the purulent forms. He next discussed a principal objection which could be raised against his views. He dealt on the importance of the tonsils forming a natural portal for the entrance of the microbes.

THE PRESIDENT thought that DR. SIMON was instead of advancing, only falling back on the old-fashioned views to which some still adhered. He doubted whether oedema of the larynx was the same thing as erysipelas of the larynx, but the one might develop from the other. He believed that there was a contagious form of catarrhal laryngitis.

DR. DE HAVILLAND HALL said he believed that erysipelas of the larynx, phlegmonous pharyngitis, and angina Ludovici were so similar, that the slight differences in their inception was not a sufficiently weighty reason to render their classification under separate heads. He recorded 7 cases, illustrative of the transmutation of one form into another. He therefore regarded them all as identical, as they presented precisely the same clinical picture.

MR. LOCKWOOD enlarged on the terms "pathological identity." He said there was a great difference between identity of "bacteriological invasion" and "identity of disease." In these inflammations about the throat and neck it was improbable that only a single species of microbes caused them all. For instance, in one case *staphylococcus pyogenes* may be found, while in another, *bacilli* (as in angina Ludovici, as evidenced by the factor, which is always due to a bacillus). Also an acute abscess in the arm may exist, due to *staphylococcus aureus*, and a peritonsillitis might be detected due to the same streptococcus, yet no one would say that the diseases in the arm and peritonsillitis were identical.

DR. SHARKEY agreed with DR. SIMON'S conclusions from a clinical point of view. He quoted 3 cases of angina Ludovici, illustrating the rapidly infective nature of the septic inflammation. They were all cases of acute primary cellulitis of the neck infecting the larynx and producing oedema of epiglottis &c.

MR. BUTLIN said that DR. SIMON'S paper only tended to make "confusion worse confounded," for he had failed to show that the diseases were alike in features, clinical aspect, appearances or pathology. No bacteriological experiments or examination had been made, and as for angina Ludovici, no accurate description of it existed. MCKENZIE had included all the other affections under one head previously, but this one.

MR. HARRISON CRIPPS related 3 cases illustrative of fatal septic cellulitis of the neck following disease (gangrene) in the thumb and face (erysipelas).

Recognition of Tubercle Bacilli in Putrid Meat.

MEAT, when kept in contact with tuberculous spurs in a moist warm atmosphere, becomes putrid in from 2 to 5 days the bacilli being readily recognized. After 10 to 25 days the pus and epithelial cells are no longer recognizable owing to dissolution. In 30 to 40 days the bacilli become granular and are less easily stained. In 40 to 60 days they undergo dissolution and are no longer recognizable. Minute sterile elastic threads are deposited quite early in the process of putrefaction. These threads are possibly caused through the transference of the bacilli into the surrounding medium through the medium and are recognizable thus. — *Transactions R. M. J.*

URBAN AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Slaughtering of Animals for Food.

Dr. DUNN, of the Alexandria Hospital at St. Petersburg, wonders as gross cruelty the methods employed in various abattoirs, and though he does not go the length of administering narcotics or anæsthetics prior to letting out the life-stream, he thinks "sheehita" or the Jewish method of slaughtering by venesection, the last civil and the most rational on chemical, economic and physiological grounds. For animals killed by the Jewish method the pain of the incision is scarcely felt, consciousness is lost in 3 to 5 seconds, 75 per cent. of the blood is lost, rigor state sets in in three or four hours, and in cold climates the meat keeps fresh for 18 days. When death is produced by stunning, the agony lasts for 15 to 20 minutes, loses only 35 per cent. of the blood, rigor mortis is delayed, and the meat will not keep for more than 18 days; when first stunned and the neck vessels afterward divided the animals suffer for a long time, lose 54 per cent. of blood, and the meat keeps fresh for 15 days only.

The Etiology of the Tight Waist.

THE hand of Science falls with a dull uncarnal thud upon the constricted waist of women. It tells why she constricts, and that the purpose from the beginning was an unholy one. The women of Decadent Greece first began it in order to emphasize the proportions of their hips and exaggerate the delusive prominence of the bosom. The simple physiological act of respiration was perverted by the tightened girdle until the act became one of sub-clavicular enticement. In fine, squeezing the waist, brought into lustful prominence the capacity of women for easy reproduction and subsequent plentiful lactation. Hippocrates denounced it in the women of Cps, GALEN reproved the practice, MARTIAL jeered at it, but still the waist was tightened and the double ovoid continued to glide before the ardent gaze of man.

The fact is, then, that women have tightened their girdles not because they wanted to do it, but because men approved of them and desired them the more for it. Why should women, then, be blamed? The practice is admitted unsound by all authorities, from HIPPOCRATES to DIO LEWIS, but men have insisted on it. Let the sanitarian and artist direct their attention, then, to man, the brute, not to woman, his victim. When this carnal but necessary factor in society and dress reform is cured of his evil ways, women will dress as they ought; but not before.—*N. Y. Med. Rec.*

Mind the Whip.

THE resident medical officer of the County Hospital at Durham sends us a note, on a sad accident which has happened before and will happen again—whose infrequency, indeed, strikes us as almost remarkable. The patient, while walking beside a cart with a friend suddenly felt that he had been struck in the eye, intense pain and total blindness being the result. A foreign body in the interior of the globe having been diagnosed, the eyeball was removed, and a knot of whipcord discovered embedded in it. This is an accident against which it would seem impossible to guard, and many of us must shudder to think that it has been no fault of our own or of our cabman that it has not happened to ourselves. In particular is it an accident likely to happen to the rider in hansom, for he cannot see the movements of the driver, which certainly conduce not infrequently to the smart flitting of the face over the face through the open window. From the expected blow, even though the period of possible expectation be of the briefest, the rider of the cab is generally safe, for the first wincing movement is to close the lids. But the rider in hansom gets no warning at all. When we intrude in our mind to estimate the number of people carried in hansom during, say, a

year, and, drawing upon personal experience, credit a large proportion of them with an unexpected stripe from the whip across the face, we wonder that more eyes are not assimilated to the unskilful or careless brandishing of the hansom cabman's whiplash.—*Lancet.*

Deaths from Syphilis.

IT is not altogether without interest, in regard to recent events, to note the ages of those who die of syphilis. According to the last report of the Registrar-General, just issued, 1,180 males died of syphilis in England in 1883. Of these, 928, or 77.9 per cent., were under 5 years of age. During the same period 964 females died of the same disease, of whom 745, or 77.2 per cent., were under 5 years of age. Various as may be the views held regarding the propriety of legislative interference with the propagation of this disease, and as to the efficacy of such means as have hitherto been proposed for that purpose, it is clear that no consideration of the subject can be complete which does not recognize the large comparative incidence of the mortality on the early years of life, the great preponderance with which the punishment falls upon the infants.—*B. M. J.*

Disintegration of Bodies after Interment.

A LECTURE on the above subject was recently delivered by DR. KRATZER, Professor of Forensic Medicine at Graz, at a meeting of the society called "Flame," which advocates the practice of cremation in Austria. The series of changes begins with the distribution of the blood. When the blood is no longer propelled by the action of the heart, it sinks to the dependent parts of the body, following the law of gravitation. The vessels soon become unable to resist the blood pressure, and the consequence is that the blood and the fluids of the tissues become extravasated, elevating the epidermis in blisters, which burst and allow all the fluid to escape. This process takes two months. From the complex molecules composing the human body more simple combinations are gradually formed, and in an early stage, the albuminates give rise to ptomaines, products resembling vegetable poisons. What we term cadaveric poisoning is not caused by the above-mentioned substances, but by living organisms. Many insects, especially flies, assist in the decomposition of the corpse. When one genus of these perishes, a second arrives to continue the work of destruction. First come the muscle destroyers, then the fat destroyers, and finally those that form humus. The soft parts of a full-grown body are decomposed within two years, a space of time which may be prolonged by want of some conditions, such as warmth, moisture, and the access of air. The fluids of the corpse generally suffice to start the decomposition; if they are deficient, the bodies turn to mummies, such as have been found in some graves of Germany and Piedmont, whereas abundance of moisture produces allpocore. Seeing that the same oxidation products (CO_2 , HNO_3 , H_2SO_4) occur in the last stage of decomposition as in combustion, these processes are to be considered as ultimately identical.—*Lancet.*

The Identification of Bloodstains.

THE third volume of *Medico-Legal Studies*, compiled and recently published by the Editor of the *Medico-Legal Journal*, New York, contains an interesting epitome of the present position of our knowledge bearing upon the identification of bloodstains. In regard to chemical tests—the guaiacum test and the production of crystals by the addition of common salt and glacial acetic acid (REICHMANN'S crystals)—it is stated that these several tests, while reliable in determining whether the matter examined contains blood or not, are of no value and throw no light whatever upon the question as to whether it was the blood of man or of animals that was examined. The application of the exceedingly delicate instrument, ROBERT'S spectroscopic apparatus, is next described,

and it is said that by its means the late DR. RICHARDSON of Philadelphia was able to detect the 1,000th part of a grain of blood on an instrument supposed to have been used in a case of suicide. The encasing section, on the value of the microscope in the differentiation of the blood of man and of domestic animals, contains a really valuable collection of material which every medico-legal practitioner would do well to have by him. The illustrations are not a matter for congratulation, but the tables of the micrometric dimensions of the blood corpuscles of mammals are useful. On the whole the conclusion—which is founded upon the evidence of well-known toxicologists like Professor THEODORE WENLEY, Professor REESE, who edited the American edition of TAYLOR'S "Medical Jurisprudence," DR. RICHARDSON of Atlantic City, DR. STEVENSON of Guy's Hospital, and others—appears to be that with a skilled and careful microscopist and a good instrument of high powers, it will generally be possible to distinguish a human bloodstain from that of any of the lower animals with the possible exception, of the guinea-pig and opossum. This subject is, however, one upon which it is well known that there exists a diversity of opinion amongst the leading authorities.

—10—

THERAPEUTICS AND PHARMACOLOGY. *Little known Properties of Chloral.*

DOCTOR HOLSTEIN calls attention to the value of chloral as a relaxant of smooth muscular fibre and a dilator of peripheral vessels. He employs it combined with iodide of sodium or potassium in bronchial asthma and hæmoptysis, where it acts by dilating the peripheral vessels.—CHERNICHEVSKY, HOKITANSKY, PAUL and others have likewise recommended chloral in connection with iodide in doses of two to three grains several times a day, and believe the chloral materially favours the action of the latter.

HOLSTEIN also employs it in minute doses in treating the coldness of feet of the anæmic, chloro-anæmic, and neuro-pathic subjects. He likewise finds it of great service in the chronic constipation of neuroathenics, which is generally so rebellious to treatment. The laxative dose is about one scruple taken before retiring, and its action is in general quite persistent, in some instances lasting several days. Like most drugs prescribed for this symptom, it is only to be employed occasionally, lest a habit be formed.—*Medical Age.*

Chronic Morphinism.

OSTEINER individualizes the treatment of the morphine habit. He suggests beginning with the average daily dose and withdrawing the dose as rapidly as the patient can bear. When the dose has been reduced to a few centigrammes, caution is necessary, as then even a slight reduction is badly borne, and at this stage warm baths of from five to fifteen minutes' duration, followed if necessary by the cold shower or cold pack from one-half to two hours (temperature from 78° to 86°F.), are often of benefit. Alcohol in liberal quantities is often useful.

Regarding cocaine he declares that in treating the morphine habit it has no other use than to modify the symptom, and should only be employed when these become violent, say twenty-four to forty-eight hours after the last dose of morphine—and should always be given by the mouth in doses of three-quarters to one-and-a-half grains, never exceeding seven grains per day. Moreover, this should be steadily reduced, and never continued longer than five or six days. Nutrition must be improved by all possible means. If collapse occurs, morphine must be resorted to. Patients with cardiac trouble should not be subjected to complete withdrawal.—*Med. World.*

Rectal Feeding.

G. STANLEY employs for this purpose the following (with or without peptonization) or milk. Peptonized milk is mixed with

certain proportions of salt, a little oil, solution of gelatin, peptin and water; this is given either daily. To prevent rectal irritation and to insure its being retained, the solution must previously be emptied by enema. If tincture of guaiacum, &c., $\frac{1}{2}$ gr. opium or 5 to 10 drops of laudanum, which are added to each nutrient enema. The diseases for which he recommends them are: hæmorrhage after gastroenteritis, to give the stomach physiological rest from the hyperæmia; peristalsis attending digestion, dilatation of the stomach; excessive vomiting of pregnancy, typhoid, and after abdominal operations. In cholera, tea and alcohol may with advantage be added to the enemata.

Acetanalid as a Surgical Dressing.

IODOFORM, owing to its penetrating odour and toxic properties, has from time to time been inveighed against, whilst mercuric bichloride corrodes instruments. It is now recommended to try acetanalid, (antilebrin) as a substitute. It is colorless, odourless, non-toxic, cheap (about 40 cents or Rs. 1-8 per pound) non-irritant and heals wounds, &c., rapidly. It is 11 times more soluble in hot than cold water, in 5 parts of alcohol, also in ether, chloroform and petroleum oils, and can thus be employed as a dusting powder (alone, or combined with starch or boracic acid), in solution (alcohol and water) as oily lotion (40 grs. to the ounce of liquid petroleum), an ointment (40 grs. to the ounce) and as a colloid (40 grs. to the ounce.) It promotes rapid healing without suppuration, drying up and soothing the parts in amputation wounds, scalds, &c. DR. THOMAS S. K. MORTON of Philadelphia has used it very extensively and successfully in his practice, and recommends its more extended trial generally.

Gout.

BOTH the following formulae gave most gratifying results to author: R *Sulphate of quinine, extract of colchicum, powdered digitalis, powdered squill*, of each 1 grain (0.065 gramme); *glycerin of tragacanth*, q. s. M. ft. pilula. Sig.: Once, twice, or thrice daily, before meals. R *Asparagin, lithii guaiacate*, of each 1½ grains (0.10 gramme). M. ft. pilula. One pill every fourth hour.—R. J. BLACKHAM, *Clinical Journal*.

Good Toast.

Is not easy to make, and yet it is one article of diet which, when made in a tempting way, is very palatable to the invalid. The aim of toasting bread is to drive out all the water in it, which tends to make it hard to digest by a weak stomach, and to give it that crisp, brown appearance. For this reason a thin piece of stale bread should be gradually exposed to a fire not too hot, but at a bright red glow. The bread should be turned over and over, and great care is necessary that it is not burned a black or even too brown, as this thick covering of burned bread keeps in the moisture and defeats the object. The toast should be a chestnut-brown.

Butter on a well-made piece of toast is not too heavy for the invalid's stomach. If the butter be spread on a piece of dark burned toast it is simply coated on the outside and reaches the stomach in lumps, but if the toast has been carefully made and the butter is evenly distributed over the whole surface of the toast, it is very digestible and can be taken with ease. When the toast is ready, it should be served at once and never left flat on a plate, but stood up on edge in a toast rack.—*Popular Health Magazine.*

Vinegar in Vomiting after Chloroform.

DR. WARHOLD has employed vinegar with success in the treatment of vomiting after anaesthesia by chloroform. He damps a cloth with the liquid and places it near the patient's nose, allowing it to remain there until he awakes, he goes longer if something then remains. He warmly recommends its use.—*Med. and Surg. Mag.*

Correspondence.

THE MEDICAL SERVICES OF INDIA AND REFORM.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

Sir,—At a meeting of the Provincial Conference recently held in Bombay, among other delegates who spoke, Dr. K. N. BANADURJI was very warmly received, and proposed that this Conference is of opinion—(1) that the present condition of the higher civil medical service is anomalous, indefensible in principle, injurious in its working, unnecessarily costly; that the hour has arrived when, in the interests of the public, medical science and the profession, as also in the cause of economic administration, the civil medical service of India should be reconstructed on the basis of such service in other civilised countries, wholly detached from and independent of its military service; (2) that the very unsatisfactory position and prospects of Civil Assistant Surgeons and Hospital Assistants compared with those of members of similar standing in other departments of the public service require thorough investigation and redress, and prays that Government will grant, for the purpose, an open inquiry by a mixed Commission of official and non-official members.

He said: Not so long ago when I urged the necessity of this important reform being voiced from the Congress platform, and being made a question more of the people than the profession, the wisdom of this suggestion was doubted in some quarters, mainly, it would seem, from fear of the monopolists securing stronger support from their official friends and patrons by reason of its connection with the Congress movement, which would seem not to command much favor in some official quarters. I say some official quarters, because it would be wrong to say that the whole official world is wholly insensible to the wholesome and helpful influence of Congress deliberations for the better understanding of the wants of the people and the Government of the country. It is true that complaints regarding the evils of the Indian Medical Service monopoly were raised from time to time, but they were invariably silenced by the Government pleading their usual *non possumus* on account of service rules and scheduled appointments. These complaints were, moreover, concerned with educational matters only, and thus touched only a small part of the entire question. And the remedy often suggested of establishing independent colleges could but satisfy in a small degree the requirements of the large and radical reform aimed at in the proposition. The objects of the reform are, as you now know, of equal importance to the people of this country and its government, no less than to its profession of medicine. For though it directly affects the emancipation of the Indian medical profession from the degradation brought on it by the Indian Medical Service monopoly, it aims nevertheless, to advance medical science itself, to enable India to learn her own medicine, to advance the material development of the country, to give the tax-payer, as we shall presently see, a genuine article fully worth the value he pays for it, and, last but not least, to give a substantial measure of relief to Government in their financial embarrassment. These are matters, you will

agree, more of public than professional interest to the country at large, and not only to the three Indian states with medical colleges, and they naturally form its subjects for consideration by our national assemblies. And we cannot but rejoice at the results which only a few meetings of our national assemblies have already worked in the matter of this important question. The educational influence of these deliberations has familiarised the people with the details of the subject, has given form to, and focussed the various defects which the reform aims at removing, and by eliciting the intelligent sympathy and co-operation of the public, helped materially to bring nearer the day for the inauguration of the reform. The various details of the evils of the present constitution of our medical services have so often been placed before the public that it would suffice on this occasion to indicate briefly only the main lines of the reform which we have been urging. A fair field and no favor, and a move with the times would express the sum and substance of our demands. It is possible, as you are aware, for our graduates in all other faculties to rise to the highest positions in the service of the State, be they those of a Law or Arts Professor, or Executive Engineer, or Collector, or Sessions, and even High Court Judge, and that without any training in Europe—a matter reflecting no small credit on the colleges and the system of education that have produced such material for State service. Why, then, should it not be equally so with our medical institutions? If the sister institutions have so creditably done their work, and it is only the medical schools that have failed to show similar results, it must be that the system of medical education, and the interests of medical science have not been entrusted to proper hands. Our present system enjoins that holders of British medical qualifications, most of which are in no way superior to our medical degrees, only if they happen to hold a commission in the army, should monopolise all the important appointments, and, as a natural consequence, our graduates in medicine, however high their qualifications or undoubted their claims to preferment, are compelled to be content with the most subordinate and inadequately paid positions in the service, and live and die Assistant Surgeons on Rs. 200 a month, while the members of the Indian Medical Service are favored with expanding military titles, and composition, military and civil allowances rising from Rs. 500 to Rs. 2,500! It is time such an anomalous and unjust system were abolished. In the name of Christian charity and British fairness, let the system, which is so grossly unfair as to condemn the non-Christian Hospital Assistant to the miserable pittance of Rs. 16 to Rs. 80 and favors his Christian brother of the Apothecary class, who undergoes similar training and faces severe tests for his examinations, with salaries ranging from Rs. 50 odd to Rs. 750 be done away with. Let it be realised that the Civil Medical Department has grown sufficiently to lead an independent life, and to have the right to take its stock from the open market of the profession, and that, other things being equal, it would be to the greater advantage of the country, both as regards economy and material progress, to have scientific of her own. Let not the choice in the equipment of its civil medical service be limited to a class of men

trained and recruited for a military service. Let not expensive military loans be any more forced on the civil department. Let it be realised that these are times for specialisation of functions, and that if science is to be cultivated for its own sake, and for the sake of the people as often avowed by Government, it requires no other qualifications from its votaries than those of merit and special training, and that, therefore, a monopoly system which requires posts to be found for men irrespective of the question of their fitness or merit, and according to which a military medical man is supposed to be fit to take up the most diverse duties at a moment's notice, be they of a professorship in a college, or of special work in a department of science, or of sanitation, or of a political agency, is not only quite out of joint with the progress of the times, but positively mischievous in its working. It was not long before public discussion of the evils of the present system took effect and official apologists not thoroughly saturated with the instincts of monopolists were forced to come out with the confession that the cry for reform had a substantial basis, only it was atrociously loud, and Government were unfortunately bound down by claims of vested rights and service schedules. But not so with some of the monopolists, themselves too far saturated with selfish thoughts to take a charitable view of the progress of science and the claims of professional brethren. These, of course, could not endorse the confession that was put forth on their behalf in the public press. They wanted a perpetuity for their monopoly, and therefore they were anxious to present a different picture altogether. And as they could not, as officials, do so in the public press, they looked round for another outlet for their version, and they hit upon a very clever plan. They held a Congress at Calcutta. They wanted non-official members, of course, for that meant money and something more, for, as the *Calcutta Medical Reporter*, first an enthusiastic supporter of that Congress, lamented, "the non-official members were deluded into attending it, and tacitly countenancing the expression of political utterances tending to their utter detriment." For, what did the President of that Congress, Dr. HARVEY, maintain as regards his men and his monopoly, and also as regards the non-official profession? "As long as the hospitals and medical schools are maintained by Government, it is reasonable that they should be officered by Government servants, and so long as Government continue to get the best men possible by open competition of the severest kind, I fail to see that there is any reason for complaint." The local graduates must, forsooth, remain content with the remnants of private practice and subordinate positions in the service, unless, indeed, they should help Dr. HARVEY to raise millions of rupees, by an increment in the salt tax, or a capitation tax, to provide for them good berths in the new municipal hospitals, or expanded health departments, which Dr. HARVEY conjured up before his mind's eye, as the only possible openings, and the only possible methods of providing them for our graduates. This is superfluous logic and uncommon sense. Does Dr. HARVEY mean that our hospitals and medical schools are not public institutions, raised and maintained by public funds, simply because they are managed by Government, and that the people who

pay for their management, have no voice in the matter of the officering and equipment of these institutions, or that the British Government is but a family of men with a number of cousins and nephews to be provided for with berths in the medical establishment, or that such as don't hold commissions in the army could not be called Government servants? The myth of the "severest competition" of the Indian Medical Service Examination, which many of our plucked students have got through with ease, has been too often exposed to need any further examination. Dr. HARVEY's millennium of expanded health departments with millions of revenue from increased salt tax, or a capitation tax, presents such an excruciatingly grotesque picture that I would not spoil its effect by any attempt at analysis. Of course, the monopolists were too shrewd not to admit the absence of scientific work in India, in spite of their unique opportunities. They admitted it, but not without deploring what they put forward as its cause, *viz.*, overwork. One medical officer, according to them had to do the work of half-a-dozen or more, and they got Mr. EUGENE HART, the editor of the *British Medical Journal*, to join in this chorus. Only Mr. HART did not know the real secret of the matter. The medical officers of the Indian Medical Service have, as their subordinates, men as qualified as themselves to do the work of the departments they are supposed to preside over. The usual routine is that papers are prepared for their signatures by these qualified subordinates, and the chiefs merely, by signing these papers, often take the credit for work, which not only have they not done, but of which they may be, and often are, altogether ignorant. But all the same they get paid for taking such inartistic credit, for they get so much extra for each department in which they sign papers. It would be superhuman, indeed, to be Health Officer, Superintendent of Jail, and several other departments, professor of one or more medical science subjects, and be engaged, practically, all hours of the day, in extensive private practice, and yet this is what happens in the case of the one and the same individual in not a few instances. The official work, perhaps, is done during night hours, for during the day they must compete with the local practitioners and, as often happens in the districts, leave the latter very little to do, so easy are their terms and so vast their opportunities from their official position. It was seriously suggested, moreover, that to enable these officials to attempt scientific work they must be provided with microscopes—why not also with pocket cases, and other requisites?—and coaching and refreshing courses in London every few months. But anything will pass for sense when coming from officials or their patrons and apologists. As soon, however, as Mr. HART began to breathe atmosphere untainted by official cant and prejudice, when he got to a safe distance from the mesmerising official radius, and was able to see things for himself, he saw quite different things, and naturally came to different conclusions, and the later views of this high authority fully and in the most unequivocal manner establish, in all important points, the position which we have taken up, and maintained and afford the most complete vindication of the justice of our complaints and the propriety of our demands, and these

opinions coming from the quarter they do, are entitled to most serious consideration. For what does he say? He condemns the present system as "radically wrong," because it gives the Indian Medical Service men duties for most of which they have no special qualification, and because a system in which "men work their way up by seniority to a position in which they fill the dual capacity of P. M. O. of the Army and Sanitary Commissioner with Government affords no guarantee that they are capable of filling the place of chief sanitary authority. And again men who had learnt their work as army surgeons at Netley, and had no preparation for the diverse duties of the Government medical service in India, could give no better productions than "mere clerk's work." It is no wonder then that India should shew utter destitution of scientific work and observation in spite of vast fields and opportunities. These are the charges against the present system regarding its serious effects on the science and profession of medicines. But Mr. HART goes further and warns the Government and the people of India that the most serious wrong that the present system "of putting men trained to work of one kind to work of quite another kind" is responsible for is, that "measures of vital importance to the health of the community are either neglected or imperfectly carried out." This one single evil of the existing system is enough to make the reform question, which we are now considering, the people's question, and to justify the public to rise up against the system, and call for immediate change. Let us hope that the public meetings which are proposed to be held all over India to voice the demand for a thorough reform of the medical administration of the country will achieve the desired success, and that the profession and the public alike will heartily co-operate to carry out the proposed scheme of securing the sympathy and support of the British public and profession, by personal pleading of our cause before them, by an accredited delegate from India. The reform, in its practical working, offers little or no difficulty, and if dispassionately viewed, it would seem to break the neck of the present system without any sudden and violent effort. Let it be clearly understood, that our civil medical officers are mere loans from the military department, and that, by force of certain schedules, the civil medical department is forced to borrow hands from this particular depôt of the I. M. S. This schedule has no legal or moral basis, for it forms no part of the I. M. S., covenant, which is for military work, and surely the medical institutions, and the various sanitary and scientific departments were not created and developed for the I. M. S. men to sponge on them. Stop then these loans, and let the civil medical service be a distinct service recruited from the open profession of medicine by selection based on merit and special training suited to its diverse requirements. Let each head and specialist of a department be the responsible and trusted adviser of Government in matters germane to his work, as is the case in every civilised country. Let hospital boards of officials and non-officials look after the hospitals and dispensaries. The civil medical service properly constituted by selection from the open profession will not only greatly advance the cause of medical education and science, but will make each district

with a hospital a centre of scientific work, and given permanence and preference to local men, good men will, surely, be attracted to the hospitals, and the knowledge and experience they will acquire will be of great local use. Why should not each hospital centre earn as much renown and shew as much good work under our graduates in the British territories as in Native States, Junagadh, for instance, where one of our local graduates has attained the high position of an authority in a special branch of Surgery? For years past the military members of the I. M. S. have been placed under the authority of the A. M. S. Surgeon-General. So far as the military medical service of India is concerned, there is practically one service under one head, with two branches, one attached to Indian troops, and the other to British troops. Why, then, have two separate enlistments of the A. M. S. and the I. M. S.? Why not have one Royal Medical Service with two branches, with the pay and pension-scale higher for the Indian troops branch than for that attached to the British troops, in consideration of its longer period of service in India. As to the reserve question, there is no reason why the civil Assistant Surgeons should not be utilised in times of war, (as pointed out by the Crawford and Cunningham Committee,) for field service, especially after their distinguished work in some former campaigns. Thus it is clear that the reform not only secures increased efficiency of the civil medical department, the rearing of medical science for its own sake and the emancipation of the medical profession, but enables Government to redeem their pledges in regard to the introduction of Western medical science in India. They have declared that colleges and hospitals have been built at public expense and by private donations for "the cultivation of medical science in the interests of humanity, and for the promotion of the happiness of the people of the country," and "not for any Governmental or executive wants," much less, therefore, as mere depôts or halting-places for unemployed military medical officers. But the reform secures another great object as welcome to the people as to the Government of the country, *viz.*, a substantial saving of some twenty lakhs a year. I will not trouble you with details, but briefly explain it thus:—There are some 370 military loans serving in the civil department. Their rank allowances come to nearly 34 lakhs a year. The replacing of these military loans by men from a reformed civil medical service consisting of the present uncovenanted grade and an improved Assistant Surgeons class, would secure a reduction of at least a third of these 34 lakhs, *i.e.*, some 12 lakhs, the scale of military allowances being a third higher than the average of the civil grade pay. But these 34 lakhs are not the actuals of the expenditure on the civil medical department, for the civil allowances of extras to these military loans cost a fourth more, *i.e.*, some 8 lakhs. The total saving, therefore, would amount to some 20 lakhs, a saving not to be despised in these hard times. That the military article is very costly, and that it would not be difficult to replace him by an equally, if not more genuine, and less expensive article, may be seen from this one fact. Side by side with his military colleagues in one of our medical colleges is working a civil professor of the same qualifications and even of the same race at a salary rising from Rs. 350 to

No. 750 only, the scale of military allowances being Rs. 750 to over Rs. 2,000! This disparity was more than once appealed against, but the Government regretted that as the civil professor was not a military man, they could not give him the allowances fixed for military loans. The resolution I have submitted to you pleads for reform with retrenchment, and increased efficiency. Whenever reforms are urged on Government they usually meet our appeal with a grievance, that they have no funds. But here is a reform which carries with it substantial redress of the standing grievance of Government. It, moreover, enables them to redeem their pledges in the matter of medical education and the introduction of Western medical science and thereby add to the sum of their beneficent work in India.

Yours &c., "TRUTH."

EXTENSION OF THE FIFTY-FIVE YEARS' RULE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—A notification has just been issued by the Government of India, the object of which is to extend the period of service for Warrant Officers in civil employ, in such cases as those in which the needful recommendation is received, beyond the age of fifty-five years. It is not easy to say what motives have actuated the Supreme Government to bring out this order. Is it that they wish to keep down the pension list, and effect a very inconsiderable saving in the Home charges, or are they actuated by a desire simply to benefit the subordinates? If this be the case, it is decidedly a new departure, because up to this time all the sugar and plums thrown out by Government have been intended for the superior and superintending grades; and the claims of the hard-working and meritorious subordinates ignored. It is a pity too, if this is really a waking up on the part of Government as to their duties to this class of servants; that they should have blundered in their first attempt to benefit them. The effect of this order will be to block the flow of promotion indefinitely, and will compel men to serve in beyond the age of fifty-five in order to gain a pension in which they can live in decency and comfort. The action of Government in this case contrasts curiously with what they did some time ago; in regard to the Civil Engineers in the P. W. D. In this case a large number were retired and compensated in order to bring about a flow of promotion; and nothing was said then about the immediate cut to the country or the permanent increase in the home charges brought about by the change. In the case of military subordinates, it is now apparent that instead of encouraging a flow of promotion, it is the intention of Government to block for an indefinite period. Looking at the question from a military point of view, it presents a curious aspect. The question is asked in the case of a man whose service is to be extended, is he physically fit? Fit for what easy and comfortable work in the military or civil branch? No doubt he is—but as each year passes, he is evidently less and less fit for even that; but what about military service? In case of a war breaking out, not one of these men would be found fit to bear the fatigue of any phase whatever of

active service, and would therefore have to be thrown away. So that in case of soldiers they cannot be considered effective after the age of fifty-five. Government might, of course, be very willing to suffer them, in the event of war; the chief points to consider are the hardship inflicted on subordinates by interposing a block to their promotion, and forcing many men to serve on beyond the age of fifty-five to gain a subsistence allowance.

Yours &c., MILLS.

A JUNIOR LECTURESHIP IN THE MADRAS MEDICAL COLLEGE FOR A HOSPITAL ASSISTANT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I read in the *Record* of the 16th March that the junior lectureship in the Madras Medical College, which has long been held by a Hospital Assistant, is likely to be given away to a member of a higher grade, on the retirement of the present incumbent; if the rumour proves to be true, the action of the authorities in power is very unjust to the already overworked and underpaid Hospital Assistants. In connection with this subject I beg to mention that originally there was only one Hospital Assistant, holding a junior lectureship in the Medical College, and that sometime afterwards, owing to increased work, another Hospital Assistant was added to the staff. The latter, on passing the L.M.S. degree, was promoted to the grade of Civil Apothecary a couple of years ago, so it will be seen that, instead of two Hospital Assistants there is only one now. The Government would have done simple justice to the Hospital Assistants if they had given the post of the L.M.S. Hospital Assistant (now promoted) to another Hospital Assistant, on the promotion of the former to a higher grade. Now if the Government again intends giving away the other only remaining appointment to a man of higher grade, that will be mere injustice. Of course there will be available many candidates holding L.M.S. or M.B. degrees for the post of a lectureship in the College outside the department. But the disposing of the only prize set apart for Hospital Assistants, in this manner will throw dust into the eyes of the deserving Hospital Assistants, who by being members of their grade, aspire to such an appointment.

It is known that Hospital Assistants cannot expect to rise in the service, unless they pass the L.M.S. Examination, and that the rules of the department are so very strict and stringent that they cannot ever dream of passing the same. Among Hospital Assistants, there are several deserving men who are matriculates, medicalists, and who have won prizes and certificates of honor. Any one who is considered the best fitted should be appointed to the post, and the Government would do more justice by thus reserving the post for a Hospital Assistant.

I beg you to kindly insert this letter in your valuable journal, and also help if necessary, by interceding on the behalf to the Local Government, before the matter is finally disposed of.

Yours &c., C. H. A.

KOLATAUR, 22nd April 1888.

THE SUBJECTS OF AN OBSTETRIC EXAMINATION.

To the Editor, "INDIAN MEDICAL RECORD."

Sir,—Kindly oblige by letting me know (1) if it is not the understood rule that the husband retires from the room while the wife is professionally examined, the examination being conducted, of course, in the presence of a female attendant or friend? (2) What does the code of medical ethics have to say about it?

Yours, &c, M. B., Abern.

[A husband usually retires while his wife is being examined.—ED. I. M. R.]

—:—:—

SHOULD A DOCTOR CONFINE HIS WIFE?

To the Editor, "INDIAN MEDICAL RECORD."

Sir,—May I trouble you for a reply to the question whether there is any breach of professional etiquette in a medical man confining his own wife?

Yours, &c., F. R. C. S. I.

[Certainly not.—ED. I. M. R.]

REVIEWS.

A MANUAL OF THE MODERN THEORY AND TECHNIQUE OF SURGICAL ASEPSIS: By CARL BECK, M.D., Visiting Surgeon to St. Mark's Hospital, and to the German Poliklinik of New York City, with 65 illustrations and 12 full page plates. Pages 306. (Published by W. B. SAUNDERS, 925, Walnut Street, Philadelphia, 1895.) Price \$ 1.25.

The above volume is one of the latest issues of SAUNDERS'S New Afl Series. It is the embodiment of the most advanced and up-to-date literature on the great subject of *Asepsis*. Although Dr. CARL BECK has limited himself to only 300 pages, (and the print is large and beautifully clear), he has within this space, packed away an immense amount of information and instruction, as only a master-teacher can do. The work is based on the methods employed by the author in the treatment of wounds at the New York Post-Graduate School and St. Mark's Hospital.

Although his aim has been to present the subject in as *practical* an aspect as possible, yet *theory* has not been altogether lost sight of, inasmuch as most of the technique of aseptic wound-treatment is founded on experiments carried on in the laboratory. Certain *minutia* (important, because their neglect mars surgical success), such as *sterilizing and disinfection of dressings* have received prominence. *Iodoform*, among antiseptics, is assigned the *locus primus* by the author: it is hence fully discussed. *Tuberculous* in relation to *asepsis* is also treated of, while the important subject of *anesthesia* (since "its inefficient mastering is apt to impair seriously the aseptic condition of the patient.") has a whole section devoted to it.

The plates and inset of the illustrations are original, being reproductions of photographs of patients and apparatus, others being taken from standard works. The author has invented a special operating suit which he has termed the "black operating suit." It is intended to be worn by the patient during operation: the site of the operation being exposed by a slit in the suit. To risk contamination and rather apt to obstruct the surgeon while operating, when too, it is apt to absorb blood, and

liquids, &c., which must remain in contact with the patient for a time at least. We prefer a good serviceable macintosh and the site of operation bare. Dr. CARL BECK has transmitted his monograph to the memory of his late teacher, "BERNHARD VON LANGENBECK, the great surgeon and philanthropist." As usual, the paper, printing, binding, &c., are of excellent quality. We have no doubt that this *theoretical-practical* treatise on *Asepsis* will hold a prominent place among contemporary literature thereon.

SANITATION AND HEALTH: a lecture delivered to the Troops at Ranikhet, by COL. REGINALD CRANE HART, V.C., B.E., Director of Military Education in India. Revised by Brigade-Surgeon Lieut.-Col. T. H. HENDLEY, C.I.E. Published by WILLIAM CLOWES and SONS, Limited, 13, Charing Cross, London. 1894. Pp. 57.

This is a capital little *health compendium*, and we venture to think it will be of more extended use than to troops merely. Its inception and birth were brought about by the exceeding unhealthiness of the rainy season of 1888; especially in the Rohilkhand District, when Colonel HART made most of the opportunity thus afforded, by delivering this lecture to the troops, then stationed at Ranikhet. Although originally intended for young officers and men coming out to India, we feel it will be none the less welcome by a large class of civilians to whom it will no doubt come as a boon, owing to its extreme portability, and the conciseness and terse manner in which it is written. It deals with every-day evils present in India, and how they may be prevented and guarded against by the exercise of common sense and sanitary precaution. It has been revised by Surgn. Lieut.-Col. T. H. HENDLEY, C.I.E.

It is one of the best little *Health Manuals* we have seen, for public use. All technical terms are avoided, and in every way, the possession of some such *read mecum* is absolutely necessary in every home. We would therefore strongly recommend the purchase of Col. HART's little brochure on *sanitation and health*, which if carefully read and followed, will, we have no doubt, be the means of preventing many a doctor's or undertaker's bill.

Government Medical Gazette.

GOVERNMENT OF INDIA.

Surgn.-Maj. H. L. Battersby, Army Med. Staff, Newpore, was in med. charge of Bundelkhand Political Agency, in addition to his milly. duties, from 21st March to 1st April.

Senior Asst. Surgn. (with hony. rank of Surgn.-Lieut.) James McNaught to be Senr. Asst. Surgn., with hony. rank of Surgn.-Capt.

First class Asst. Surgn. Charles Atkins to be Senr. Asst. Surgn. with hony. rank of Surgn.-Lieut.

Second class Asst. Surgn. George How Crowe to be first class Asst. Surgn.

Third class Asst. Surgn. William Jeremiah Phillips Martin to be 2nd class Asst. Surgn. from 1st Dec. 1894, vice Senr. Asst. Surgn. (with hony. rank of Surgn.-Capt.) Henry James Miller, retired.

Second grade Hosp. Asst. Shiu-mahar Lal, attached to No. 14 Himalaya Sanitary Party, is apptd. in addition to his own duties, to Station Sanit. Depy., Simla, during absence on deputation of Civil Hosp. Asst. Subramanyam Khan.

Mr. U. Banks, M.A., C.M., B.F.S., is conferred in Lieutenant. Med. Service, and his services are placed permanently at disposal of Govt. of Hong. from 1st Nov. 1902, when he was apptd. Civil Med. Offr. of Yankhai.

Services of Surgn.-Col. J. H. Newman, M.D., I. M. S. (Beng.) Ready, Surgn. and Chief Med. Offr. in Rajputana, are placed at disposal of Home Dept. from 29th March.

Surgn.-Maj. George Tucker Thomas, Arthur James Sturmer, Archibald Adams, M.D., have completed twenty years' full pay service and are to be Surgn. Lieut.-Cols., 31st March.

Surgn.-Capt. Arthur Owen Evans has completed twelve years' full pay service and is to be Surgn.-Maj.

Surgn.-Lieut.-Col. Arthur Lake Hackett, I. M. S. (Mad.), Surgn. 2nd Dist., Madras, is permitted to retire from service, from 4th May.

Senr. Asst. Surgn. and Henry. Surgn.-Capt. J. Hamilton, attached to Med. Store Depot, Calcutta, is granted 80 days' priv. leave from 5th May.

Senr. Hosp. Asst. Deo Dutt Panday returned to duty and resumed Sub-med. charge of Ready, Hosp. Nepal, on 31st March.

The services of Surgn.-Lieut. W. Young, M.B., C.M., I. M. S. (Beng.) are placed temply. at disposal of Govt. of N.-W. P. and Oadh.

Surgn.-Capt. H. E. Drake-Brockman, I. M. S. (Beng.) on mly. duty, Nowgong, is apptd. to med. charge of Bundelkhand Political Agency, in addition to his mly. duties, from 2nd April.

Surgn. Lieut.-Col. Frederick Augustus Smyth to be Brig.-Surgn. Lieut.-Col., 12th Jany.

Surgn.-Lieut. Bruce Gordon Seton to be Surgn.-Capt., 30th Jany.

Surgn.-Lieuts. Robert Henry Elliot, Robert King Mitter, Wilfred Ernest Arbuthnot Armstrong, to be Surgn.-Capts., 30th Jany.

Surgn.-Lieut. William Carr Sprague, M.D., to be Surgn.-Capt., 30th Jany.

Brig.-Surgn. Lieut.-Col. W. R. Hooper, I. M. S., granted temply. rank of Surgn.-Col. whilst Preslt. of Med. Board, India Office, 24th April.

Surgn.-Maj. H. N. V. Harington, I. M. S. (Madras), Offg. Ready, Surgn. in Meywar, granted priv. leave for two months from 15th instant.

Surgn.-Maj. J. Crofts, M.D., I. M. S. (Beng.) Med. Offr. of the Kotah and Jhalawar Agencies, availed himself, on 7th instant, of priv. leave granted him on 29th April.

BENGAL GOVERNMENT.

Surgn.-Col. R. D. Murray made over charge of Chittagong Jail to Surgn.-Maj. J. Lewtas on 7th April.

Asst. Surgn. Bana Mali Roy, doing superny duty at Medical College Hosp., is apptd. to do superny. duty at Presdy. Genl. Hosp.

Surgn.-Capt. T. Grainger, Offg. Civil Surgn. of Noakhali, is apptd. to act as Civil Surgn. of Hooghly during absence of Surgn. Lieut.-Col. Bussik Lal Dutt.

Surgn. Lieut.-Col. A. Crombie, Surgn. Supdt. of Presdy. Genl. Hosp., is allowed priv. leave for one month and nineteen days.

Surgn.-Capt. H. W. Pilgrim, Offg. First Resdt. Surgn., Presdy. Genl. Hosp., is apptd. to act as Surgn. Supdt. of that institution, during absence, on leave, of Surgn.-Lieut.-Col. A. Crombie.

Surgn.-Maj. A. Keogh, Med. Staff, is apptd. to have charge of civil med. duties at Barrackpore, in addition, to his own duties, from 5th April.

Surgn.-Capt. J. E. Panloto, Second (Cadet) Battalion, Calcutta V. B. Co., is allowed leave of absence for three months from 18th April.

Asst. Surgn. Surendra Nath Dutt, offg. at Lalbag Disp. in Murshidabad Dist., is confirmed in that appointment.

Asst. Surgn. Motbura Nath Sen, offg. at Madhubani sub-divn. and disp. in Darbhanga Dist., is confirmed in that appointment.

Asst. Surgn. Haril Charan Sen is apptd. to do superny. duty at Med. Coll. Hosp.

Surgn.-Capt. T. Grainger made over charge of Noakhali Jail to Moulvi Abdul Kadir on 2nd May.

Moulvi Abdul Kadir made over charge of Noakhali Jail to Asst. Surgn. Ganga Govinda Sarkar on 6th May.

Surgn.-Lieut.-Col. B. L. Dutt made over charge of Hooghly Jail to Surgn.-Capt. T. Grainger on 5th May.

Asst. Surgn. Khirede Chandra Chowdhuri apptd. to do superny. duty at Campbell Med. School and Hosp. until further orders, from 5th April.

Asst. Surgn. Kuthja Lal Banya, Offg. Teacher of Med. and Midwifery in Dacca Med. School, confirmed in that appointment.

Asst. Surgn. Mohindra Lal Mitter, a superny. at Med. Coll. Hosp., Calcutta, allowed leave for three months.

PUNJAB GOVERNMENT.

Surgn.-Capt. F. B. Ozardi made over charge of duties of Supdt. of Abbottabad Jail to Surgn. Lieut.-Col. J. T. B. Bookey on 18th April.

Surgn.-Capt. W. R. Clark made over charge of duties of Supdt. of Ferozepore Jail to Surgn.-Capt. A. Guist-Sparks on 6th April.

Asst. Surgn. Sahib Ditta, doing genl. duty at Amritsar, is apptd. to offe. as Civil Surgn. of Gujrat from 27th April, vice Surgn.-Capt. H. M. Morris, transferred.

Asst. Surgn. Mul Chand, Mooltan Civil Hosp., is apptd. to offe. Civil Surgn. of Mooltan, from 27th April in addition to his other duties, vice Surgn.-Capt. W. R. Clark, transferred.

Surgn.-Capt. W. R. Clark is apptd. to offe. as Civil Surgn. of Lahore Supdt. of Lahore Lunatic Asylum, from 29th April, during absence on furlough of Surgn.-Maj. W. Coates.

First class Hosp. Asst. Nur Bukhsh, Dera Ismail Khan Jail Hosp., has obtained seven months' furlough, and was relieved of his duties on 25th April by 2nd class Hosp. Asst. Hakim Bai, transferred from Bhakkar.

Asst. Surgn. Duni Chand Rai, from Jagadhri Disp., Umballa Dist., to Bhiwani Disp., Hissar Dist., which he joined on 26th April, relieving Asst. Surgn. Hira Lal.

Third class Hosp. Asst. Radha Kishen, Gungera Disp., has obtained 45 days' priv. leave from 20th April.

The following newly passed Hosp. Assts. were granted one month's leave on full pay from dates mentioned opposite their names—

Hosp. Asst. Lahoria Ram, 1st November 1894; Hosp. Asst. Amir Khan, 20th Nov. 1894; Hosp. Asst. Ganesh Das, 18th Nov. 1894.

On return from the one month's leave, 3rd class Hosp. Assts. Lahoria Ram, Amir Khan and Ganesh Das reported themselves, respectively, to Civil Surgns. of Ferozepore, Karnal and Delhi for genl. duty on 18th, 25th and 26th Dec. 1894.

The following transfers were made in Delhi Dist., in interests of public service:—Second class Hosp. Asst. Dilwar Ali, from Najafgarh to Okla Canal Disp., 14th April.

Second class Hosp. Asst. Abdul Karim, from Okla Canal Disp. to Jail Hosp., 18th April.

First class Hosp. Asst. Fakir-ulla, from Delhi Jail to Najafgarh Disp., 22nd April.

Surgn.-Capt. H. M. Morris assumed charge of civil med. duties of Mooltan, on 1st May, relieving Asst. Surgn. Mool Chand.

Sheikh Miran Bakhsh, Extra Asst. Commr., held charge of duties of Supdt. of Hoshiarpur Jail from 25th March to 3rd April.

Surgn.-Capt. W. R. Clark made over charge of duties of Supdt. of Mooltan Dist. Jail to Asst. Surgn. Mool Chand on 27th April.

Surgn.-Capt. H. M. Morris made over charge of duties of Supdt. of Gujrat Jail to Asst. Surgn. Sahib Ditta on 27th April.

Surgn.-Maj. S. F. Bigger made over charge of duties of Supdt. of Bannu Jail to Surgn.-Capt. H. Fooks on 30th April.

MADRAS GOVERNMENT.

Surgn.-Maj. Winthrop Benjamin Browning to be Surgn., Second Dist., Madras, in succession to Brig.-Surgn. Lieut.-Col. A. L. Hackett, retired, but to continue to be Surgn. to H. E. the Governor until further orders.

Surgn.-Maj. Donald Frederick Dymott, M.B., to act as Surgn., Second Dist., Madras, during employment of Surgn.-Maj. W. B. Browning on other duty, or until further orders.

Surgn.-Maj. Francis Casement Reeves to be Dist. Med. and San'y. Offr. and Supdt. of Jail, Madura.

Surgn. Lieut.-Col. Thomas James Hackett Watkins to be Dist. Med. and San'y. Offr., Malabar, to act as Dist. Med. and San'y. Offr., Salem, during absence of Surgn.-Lieut.-Col. S. N. Roberts-Harrison on leave, or until further orders.

Surgn.-Capt. Frank Charles Penrice to be Dist. Med. and San'y. Offr., Coimbatore, and Supdt. of Jail, Berhampur, in succession to Surgn. Lieut.-Col. T. J. H. Watkins.

BENGAL GOVERNMENT.

Surgn-Maj. R. Aker is apptd. to act as Civil Surgn. in addition to his own duties, from 30th April.

Asst. Surgn. Ramabandha Bhattacharya, L.M.S., has been placed on genl. duty from 3rd April.

Asst. Surgn. Matilal Gangadass Desai, L.M.S., allowed priv. leave for one month and fifteen days.

Surgn-Maj. A. E. J. O'Leary, F.R.C.S., apptd. to act temply. as Civil Surgn. at Batare, in addition to his own duties, vice Surgn.-Lieut. B. H. F. Leumann, M.B., transferred, from 1st April.

Surgn-Maj. J. McCloghry and G. E. Fooks respectively transferred over and received med. charge of Ahmetabad Central Prison on 30th April.

Asst. Surgn. Darabala Edulji Kothavala, L.M.S., has been apptd. to act as Supdt. and Med. Offr. Siml Convict Hosp. from 11th March, during absence of Asst. Surgn. George M. Dixon, L.M.S., granted furlough.

CENTRAL PROVINCES GOVERNMENT.

Second class Civil Hosp. Asst. Nanak Parshad, doing duty at Barhampur Disp., Nimar Dist., directed to do duty under orders of Civil Surgn., Pachmarhi.

Surgn.-Capt. C. N. Bensley, Civil Surgn., permitted, by Her Majesty's Secy. of State for India to return to duty within period of leave granted him.

Second class Civil Hosp. Asst. Syad Muhammad Hahlar Hussain Haidari, attached to Main Disp., Khandwa, hold temp. med. charge of Nimar Dist., from 27th Feb. to 18th March, in absence of Civil Surgn.

First grade Asst. Surgn. J. W. Hogan, whose services have been placed at disposal of Chief Commr., Central Prov., by Surgn.-Genl. with Govt. of India, is apptd. to offic. as Civil Surgn., Wardha.

Asst. Surgn. J. W. Hogan, Offg. Civil Surgn., Wardha, to exec. and med. charge of Wardha Jail.

Asst. Surgns. E. P. Clements and J. W. Hogan, respectively made over and received exec. and med. charge of Wardha Jail on 18th ultimo.

N.W.P. AND OUDH GOVERNMENT.

Surgn-Maj. T. H. Sweeney, Civil Surgn., from Fyzabad to Benares as offg. Civil Surgn., 1st class.

Brig-Surgn. Lieut.-Col. R. Jameson, Depy. Sany. Commr., 1st Circle, N.W. P. and Oudh, offd. as Sany. Commr. N.W. P. and Oudh, in addition to his other duties from 30th March to 11th April.

Surgn-Maj. D. F. Barry, Civil Surgn., from Sitapur to Gorakhpur.

Surgn-Maj. C. O. Vaid, Civil Surgn., from Kheri to Sitapur.

Surgn-Maj. C. P. Lukie, Civil Surgn., from Shahjahanpur to Fyzabad.

Surgn-Maj. J. C. C. Smith, Civil Surgn., from Bara Banki to Shahjahanpur.

Surgn-Maj. G. A. Emerson, Civil Surgn., from Jaunpur to Jhansi.

Surgn.-Capt. L. G. Fischer, Civil Surgn., from Budaun to Meerut.

Surgn.-Capt. J. M. Cadell, Offg. Civil Surgn., on completion of special duty, to civil med. charge of Etawah Dist.

Surgn-Maj. T. H. Sweeney, Civil Surgn., Benares, to hold visiting med. charge of Saugor Dist. in addition to his other duties.

Surgn-Maj. G. C. Vaid, Civil Surgn., Sitapur, to hold visiting med. charge of Kheri Dist. in addition to his other duties.

Surgn-Maj. C. P. Lukie, Civil Surgn., Fyzabad, to hold visiting med. charge of Bara Banki Dist. in addition to his other duties.

Surgn-Maj. J. F. Zeeby, Civil Surgn., Saharepur, to hold visiting med. charge of Saharepur Dist. in addition to his other duties.

Surgn.-Capt. L. G. Fischer, Civil Surgn., Meerut, to hold visiting med. charge of Budaun Dist. in addition to his other duties.

Asst. Surgn. Subhishil Das, in charge of Kotar Disp., to hold civil med. charge of this dist. in addition to his other duties.

Asst. Surgn. Chandra Kanta Chakrabarti, in charge of Kotar Disp., to hold civil med. charge of this dist. in addition to his other duties.

Asst. Surgn. Hari Gopal Chakrabarti, in charge of Kotar Disp., to hold civil med. charge of this dist. in addition to his other duties.

Asst. Surgn. Anwar Most. Khan, in charge of Kotar Disp., Jaunpur, to hold civil med. charge of this dist. in addition to his other duties.

Asst. Surgn. Kotar Nath Sen, in charge of Kotar Disp., Budaun, to hold civil med. charge of this dist. in addition to his other duties.

Surgn-Maj. P. J. Freyer, Civil Surgn., Benares, leave (M.C.) out of India for six months from 1st May.

Surgn-Lieut. Col. E. Mair, Supdt. Central Prison, Meerut, priv. leave for three months from 1st May.

Surgn-Maj. J. Anderson, Civil Surgn., Bareilly, to hold charge of Central Prison, Bareilly, in addition to his other duties.

BURMA GOVERNMENT.

First grade Hosp. Asst. Nissari Htoo relinquished charge of Outpost Hosp. N'Krong, Myitkyina Dist. on 1st March and assumed charge of Civil Disp., Myitkyina, on 1st March.

Second grade Hosp. Asst. Shahr Abdulla, on arriving himself of priv. leave for three months relinquished charge of Contagious Diseases Hosp., Rangoon, on 23rd April.

Second grade Hosp. Asst. Jogen-ra Nakh Blatrecchari relinquished charge of Genl. Hosp. Rangoon, on 23rd April and assumed charge of Contagious Diseases Hosp., Rangoon, on 24th April.

Second grade Hosp. Asst. Khudabarith on resigning on special cholera duty at Kungyangon, Hantawaddy Dist., relinquished charge of Genl. Hosp., Rangoon, on 24th April.

Third grade Hosp. Asst. Maung Lu Gale, on proceeding to Bhamo to give med. evlcnce before Sessions Judge, relinquished charge of Civil Hosp., Myitkyina, on 3rd March, detained at Bhamo up to 9th March.

Third grade Hosp. Asst. Maung Lu Gale, priv. leave for three months, from 10th March.

Third grade Hosp. Asst. K. Perumal Pillay relinquished charge of Police Hosp., Katha, on 2nd April, and assumed charge of Outpost Hosp., Mohayin, Katha Dist., on 2nd April.

Third grade Hosp. Asst. Tjijung Koonin relinquished charge of Outpost Hosp., Mohayin, Katha Dist., on 2nd April and assumed charge of Police Hosp., Katha, on 1st April.

Third grade Hosp. Asst. Kodas Chander, on resigning charge of Police Hosp., Bhamo, on 26th March, and assumed med. charge of Kungtung Rd. Survey Party, at Fort Steelman, on 16th April.

Third grade Hosp. Asst. Raghunatha Singha relinquished charge of Police Hosp., Bhamo, 15th April, and assumed charge of Outpost Hosp., Myothit, Bhamo Dist., on 17th April.

Third grade Hosp. Asst. Shyam Khoro Day relinquished charge of Outpost Hosp., Myothit, Bhamo Dist., on 17th April and assumed charge of Police Hosp., Bhamo, on 19th April.

Third grade Hosp. Asst. Shyam Khoro Day, priv. leave for three months, relinquished charge of Police Hosp., Bhamo, on 22nd April.

The services of second class Mily, Asst. Surgn. R. W. A. L'Ettrange are placed at disposal of Chief Commr. of Burma.

Surgn.-Capt. C. W. Johnson, M.B., made over and Surgn.-Lieut. H. W. H. Reilly, M.B., assumed, as collateral charge, duties of Civil Surgn., Meiktila, on 30th April.

Surgn.-Capt. K. Prasad made over, and Surgn.-Capt. F. W. Gibbard, A.M.S., assumed as collateral charge, the duties of Civil Surgn. Shwebo, on 30th April.

Surgn.-Capt. A. R. P. Russell made over, and Surgn.-Capt. K. Prasad assumed, charge of duties of Civil Surgn., Tongue, on 3rd May.

Surgn. Lieut.-Col. O. Baker made over, and Surgn-Maj. R. E. S. Davis, M.B., assumed charge of duties of Senior Civil Surgn. and Supdt., Lunatic Asylum, Rangoon, on 1st May.

Third grade Local Asst. Surgn. Maung Tato, on proceeding to Rangoon for promotion exam., relinquished charge of Civil Disp., Allampon, Thabemye Dist., on 1st May.

First grade Hosp. Asst. Allamin, on return from leave, assumed charge of Civil Disp., Allampon, Thabemye Dist., on 1st May.

Second grade Hosp. Asst. D. DeSouza relinquished med. charge with M.C. service at Bhamo on 10th March and assumed charge of Police Hosp., Bhamo, on 10th March.

Second grade Hosp. Asst. D. DeSouza relinquished charge of Police Hosp., Bhamo, on 26th March and assumed charge of Jail Hosp., Meiktila, on 26th March.

ASSAM GOVERNMENT.

Priv. leave for one month granted to 3rd grade Hosp. Asst. Nalini Kanta Sen Gupta, in med. charge of Nokhila Disp. in Naga Hills Dist. from 27th April.

Third grade Hosp. Asst. Syed Abdul Jalal, a superny. in Naga Hills Dist. is appld. to med. charge of Nokhila Disp. in that Dist. from 27th April, during absence on priv. leave of 3rd grade Hosp. Asst. Nalini Kanta Sen Gupta.

Priv. leave for three months is granted to 3rd grade Hosp. Asst. Kamal Charan Datta, in med. charge of Chief Commr's Staff, from 3rd May.

3rd grade Hosp. Asst. Nil Kanta Sen, a superny. in the Darrang and Jaintia Hills Dist., is appld. to med. charge of Chief Commr's Staff from 3rd May, during absence on priv. leave of 3rd grade Hosp. Asst. Kamal Charan Datta.

Priv. leave for three months is granted to 2nd grade Hosp. Asst. Ram Charan Panlay, in sub-med. charge of Jail and Police Hospitals at Tezpur in Darrang Dist. from 3rd May.

Third grade Hosp. Asst. Chandra Kisor De, a superny. in Darrang Dist., is appld. to sub-med. charge of Jail and Police Hosps. at Tezpur, from 3rd May, during absence on priv. leave of 2nd grade Hosp. Asst. Ram Charan Panlay.

Babu Nalini Kanta Sen Gupta is confirmed as a 3rd grade Hosp. Asst. in Assam from 30th Oct. 1894.

Babu Chandra Kisor De is confirmed as a 3rd grade Hosp. Asst. in Assam from 22nd April.

Third grade Hosp. Asst. Kumudini Kanta Chakravarti, in med. charge of coolies on the Nicheguard-Manipur Road, is appld. a superny. in Naga Hills Dist. from 4th April.

Sick leave for twenty-two days, granted to 3rd grade Hosp. Asst. Kumudini Kanta Chakravarti, a superny. in Naga Hills Dist. from 12th April.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

MAHONEY.—On 20th April, at Madras, the wife of Asst. Surgn. C. Mahoney, 5th Infy., Hyderabad Contingent, of a son.

STEVENSON.—On 16th May, at Lanowli, the wife of Surgn.-Maj. Stevenson, I. M. S., of a son.

DEATHS.

CARTER.—On 4th May, at Budleigh Salterton, Henry John Carter, F.R.S., retired Surgn.-Maj., Bombay Army, aged 82 years.

DEANE.—On 7th May, at Naini Tal, Surgn.-Maj. W. Deane, F.R.C.S.I., Civil Surgn., Moradabad, N.-W. P., aged 39 years.

GUNNING.—On 1st May, Brig.-Surgn. Lieut.-Col. James Davis Gunning, A.M.S., on board the troopship *Malabar*, one day out from Gibraltar, homeward bound, aged 50 years.

HARPER.—On 3rd May, at Abingdon Road, Kensington, W. Henry Harper, Deputy Surgn.-Genl., Madras Medical Service (retired).

MOOREHEAD.—On 6th May, at Margate, Edward Moorhead, M.D., Deputy Insp.-Genl. (retired) Army Med. Dept. aged 76 years.

NOTICES TO CORRESPONDENTS.

A. L. M. (Jalpaiguri).—We will do our best for you gladly.

W. J. M. (Bain).—The information you seek had better be obtained direct from the Surgeon-General with the Government of India.

D. P. (Government College, Jabalpur).—Your request was attended to in a previous number. The *Ganjinia Tibbat* is published in Lahore. Send your order to our manager for any medical works you need.

S. N. G. (Calcutta).—We regret the long delay, but sincerely hope for the leisure that will enable us to fulfil the task.

A. C. T.—Your claim is a very fair one, and we wish you success.

S. R. P. (Hati Mardan).—Yes, look up the published list.

M. (Cutch).—Look up Corna's "New Boundies."

M. L. (Gangavati).—The subscriptions for the *Record* and the Indian Medical Association are separate. The fee for the latter is Rs. 5, and you will find full particulars for the former in our "Business Notices."

J. P. (Manipur).—You have our sympathy, but we can only counsel further patience.

We are grateful for many contributions received, both for our "Original" columns and "Mirror of Practice." We would congratulate our co-workers.

ACKNOWLEDGMENTS.

We acknowledge receipt of the following with thanks:

A CHLOROFORM ACCIDENT: A COMMENTARY ON THE THEORY OF "HEART FAILURE."

By SURGEON-CAPTAIN PATRICK HEER, M.D.,
F.R.S.E., F.R.C.S.E., D.P.H., (Cantab.)

Lecturer on Medicine and Pathology,
Hyderabad Medical School.

THE following case of resuscitation from apparent death from chloroform narcosis is probably one of the most interesting on record, and a review of the circumstances connected with it will shew that it is probably quite unique amongst cases of the kind.

I happened to visit the Afzul Gunj Hospital (the General Hospital of Hyderabad, Deccan.) on the morning of the 13th September 1894, to see Surgeon-Lieutenant-Colonel LAWRIE perform an exploratory laparotomy, preliminary to ovariectomy, on a woman about 60 years of age; but, in addition to the operation, I had an unexpected experience, which gave me a strange and serious lesson in chloroform administration.

The patient was brought into the operating theatre about 8-30 A.M. having previously received a hypodermic injection of quarter of a grain of morphine. I was kindly invited to examine the patient, who was a shrivelled up old woman without a particle of fat on her body. The abdominal cavity was enormously distended, somewhat globular, the greatest girth measurement being over the umbilicus; the surface was glistening, and several large veins passed over it in various directions; it was tense and highly elastic, dull on percussion over the whole abdomen (including the hypochondriac and lumbar regions), except over one small area in the epigastric region.

Immediate percussion shewed that the peritoneal cavity was enormously distended with fluid, but on firm sharp "pitting" one felt an irregular tumour-like mass, situated in the hypogastric, two iliac, and part of the umbilical regions. The apex-beat of the heart was seen to correspond with the 3rd interspace, just inside the nipple line, and although the tumour mass did not move on respiration, the upper part of the chest (from the 5th rib upwards) moved freely; the pulse was small, frequent, and of fair tension, and gave me the idea of the arteries being arteriosclerotic, which the tortuous superficial temporal vessels tended to confirm. The high tension of the abdominal walls, the depth of the tumour, and the fact that being a Mahomedan woman, a vaginal examination could not be made, rendered a positive diagnosis impossible. Provisionally it was diagnosed as an ovarian tumour, probably solid, requiring an exploratory laparotomy.

Chloroformisation was commenced, and up to the time two drachms had been administered, nothing unusual took place. The pulse and respiration were regular. Whilst the third drachm of chloroform was being administered, I heard the patient make a peculiar guttural noise, but I was not near enough to recognise whether she was snoring. Afterward, one of the students standing by the

patient's head remarked "snoring," after which Dr. LAWRIE, who was recording the events during the chloroformisation, said "noisy expiration," and remarked at the same time, that he did not hear actual snoring. The great protuberance of the patient's abdomen prevented the visitors who were sitting in the front seats of the operating theatre and on a level with the patient, from actually seeing the respiratory movements. Nevertheless, I noticed that from the time Dr. LAWRIE said "noisy expiration," his attention was rivetted on the patient's respiration, which, apparently became shallower and shallower. The chloroformist then said "respiration stopped," and pushed the patient's jaw forward. Dr. LAWRIE thereupon ordered the tongue to be drawn out of the mouth with a forceps and at once began artificial respiration, standing on one side of the patient, but after making a few compressions, finding artificial respiration in that position ineffectual, he jumped on to the table and began Howard's direct method of artificial respiration, the patient's head being at the same time drawn over the end of the table, and the neck put on the stretch. As soon as Dr. LAWRIE got on the table, I stepped forward, and at Dr. LAWRIE's request, tapped the abdominal cavity in the usual place for ascites—a bloody serum immediately spurting out of the cannula with great force. Even Howard's method proved futile—the walls of the chest appearing to be perfectly inelastic. Dr. LAWRIE then (whilst continuing the artificial respiration), tried direct mouth-to-mouth inflation of the lungs, and after several attempts the patient gasped feebly; this process of inflation being continued by Dr. LAWRIE, the House Surgeon, Dr. ABDUL HOSSEIN, and myself in turns, until eventually the patient took one deep inspiration, followed by a series of others, and in about ten seconds respiration became quite regular once more.

The whole of the above transpired in a considerably shorter period than it has taken me to describe it. I learnt afterwards that the record showed that the patient had ceased to breathe for fully six minutes, whilst the pulse continued to beat for two minutes after the respiration had stopped; but as it had ceased to be felt at the wrist, life seemed apparently extinct. No doubt the heart was acting, but Dr. LAWRIE abstained from attempting to ascertain that fact, recognising that even a few seconds lost at such a critical time was of vital significance to the success of the measures of resuscitation.

The distension of the abdomen had created the utmost condition of tension. The pressure, like hydrostatic pressure wherever it is met with, exerted its effects equally in all directions upon the arch of the diaphragm, and through it on the lungs and heart, upon all the blood vessels at the back of the abdominal cavity, &c.

The lungs admitted a comparatively small quantity of air, to compensate which, there was increased frequency in respiration.

In this case had the pulse, (which was fairly good for about three minutes after the cessation of respiration) been taken as a guide, a period of time would have been lost which would probably have ended the patient's life. By watching the patient's respiration, not only was the stoppage noted, but the fact that this breathing was gradually

becoming more and more shallow was also observed, and the chloroformist and those noting the state of the patient's respiration, were ready to perform artificial respiration.

There could not have been a worse case than this, in which to administer chloroform, nor one in which to resuscitate when an over-dose had been given, because of a dilated and weak heart, whose normal action was mechanically interfered with, diseased arteries, compressed lungs, &c. The comparatively small lung area and weak heart were however, I believe the reasons why she did not get an over-dose earlier; because with a smaller area for absorption in the lungs, less chloroform was absorbed by the pulmonary capillaries, and with a small weak heart, less was discharged into the respiratory and other nerve centres. Were chloroform to act directly on the heart, it is almost impossible to conceive how in this case resuscitation could have taken place; for it was laboring under such insuperable disadvantages, (besides that of prolonged malnutrition as a result of bad circulation in the probably diseased coronary arteries,) that it must have failed. Further, why should a few respiratory movements have restored to the heart full vigour once more? The removal of the fluid by aspiration no doubt had a great deal to do with the recovery of the patient, by at once giving a larger breathing surface, and by removing the pressure on the diaphragm and the pericardial sac.

The phenomena co-existing in this old woman's case render it comparable with the important experiment of the 2nd Hyderabad Chloroform Commission, which shewed that fatty degeneration of the heart (artificially produced by phosphorus poisoning), induced a certain amount of safety under chloroform; for in this latter case the smaller the quantity of chloroform thrown into the lungs, the nervous system and the coronary arteries by the weak fatty heart, the less chloroform reached the nerve centres, and especially the respiratory centre. It is quite possible that in this case elimination of chloroform was interfered with more than it is under ordinary circumstances; for inspiration being accomplished with a certain amount of facility, on account of the development of the extraordinary muscles of respiration; expiration was less vigorous than usual, because of (1) the loss of function of the abdominal muscles; and (2) partial absence of the elastic recoil of the lungs and the chest walls, which was prevented by the pressure from below, and of the chest walls from senile changes in the ribs. It may be remarked also that the great interference with the action of the diaphragm as an inspiratory muscle must have also considerably reduced the amount of chloroform inhaled at each inspiration.

Another curious fact about this case appears to be that the patient presented none of the symptoms of asphyxia, but rather those of gradual cessation of both the respiratory and cardiac functions. I do not offer any opinion as to why this comparatively small quantity of chloroform should have produced the effects it did in this case, beyond that inferentially given. Under any circumstances, I would state that cases of this kind require the greatest possible amount of watching and care during chloroform administration, and even

with these precautions, I believe, that it is impossible to avoid accidents such as this one was. I have tried to explain. An important question arises out of the circumstances of this case, namely—Could this accident have been avoided, and yet the patient got safely under chloroform? The answer I would give is: Yes, if it were given very slowly; and if, as a preliminary measure, the ascitic fluid were evacuated. This case teaches another important fact—that it is advisable in all such cases to evacuate a part at least, of the ascitic fluid before chloroformisation, when there is such enormous distension, especially in old people. If the accident had not taken place when it did, it is very likely it would have occurred somewhat later, after a large incision had been made in the abdominal walls, and under circumstances which would have been obviously very disastrous. There is no doubt, also, but that the pressure of the ascitic fluid upon the inferior vena cava considerably decreased the blood going to the lower extremities—most of that which was poured into the aorta at each beat of the heart going to the nerve centres of the brain. I entertain the strongest conviction that were it not for the direct inflation, the patient's life would have been lost. Indeed it was practically the only means we could have adopted with success. It may be an exceedingly unpleasant method, but the object in view is to save the life of our patient, and any means by which we can do this must have something to support it. In the case under observation, the process was excessively unpleasant, but we were rewarded sufficiently by the result which immediately followed.

I believe that in cases of this kind in England, ether would be specially chosen for the purpose of stimulating the heart and resuscitating the patient; whereas all those who had anything to do with the Chloroform Commissions of Hyderabad know that with a rapidly decreasing blood-tension, the introduction of ether has a powerfully accelerating effect upon the descent of the needle of the manometer. Experiment No. 72 of the 2nd Hyderabad Chloroform Commission forcibly riveted this fact upon my mind. The details of this experiment (which will be found in the report of the Hyderabad Chloroform Commission); proved these facts unequivocally, and may be referred to by those interested in this point.

Per contra, it was shown in the same experiment and in several others, that when the tension was not low, that is, when it is fairly good and not declining, the introduction of ether subcutaneously, raised the blood-tension in the vessels. These are not the cases which need any stimulation. I therefore feel convinced that the practice of introducing ether in cases of chloroform accidents, and especially in those of the so-called "cardiac failure," (if there be such thing), is false in principle, and opposed to scientific experience. It would be equally justifiable to introduce hydrate of chloral subcutaneously, or even chloroform itself, for the same purpose. In several former communications to the medical press, I have attempted to point out this point, but ether is still given hypodermically, and sometimes still off chloroform poisoning, in whom ether has been thus administered. In most of the fatal cases of chloroform poisoning in which ether is thus administered, the ether

has absolutely nothing to do with this untoward result, because the peripheral circulation is absent, or so feeble, that no absorption can take place either through the lymphatics or capillaries of the circulatory system. And in other cases where patients recover in which ether is administered, I believe they do so in spite of, and not as a result of the use of the ether.

Regarding the accident under review, the ordinary opinion would be that it was the result of an overdose, and possibly in this particular case this may have been so, and the question then arises—How could the accident have been avoided? The answer to this involves a consideration of the whole principles of chloroformisation. Granting that an operation was necessary (and of that there was no doubt), and that chloroform had to be administered, all we could do was to follow rigidly the principles of administration ordinarily followed by SYME, LAWRIE, and their followers. The case was undoubtedly an exceptional one but if we once start creating rules for exceptional cases, a confusion will arise which will confound chloroformists, and hopelessly perplex the beginner. It might be said that *special* caution should be observed in a case like this, but we hold that without *special* caution in every case of chloroform administration the patient's life is placed in jeopardy. In this case the administration was superintended by Surgeon Lieutenant-Colonel LAWRIE himself, and in stating this we need state no more about attention as to the administration.

Then we come to the question—What is an overdose? As there is such a thing as an overdose in other poisons, so there is in chloroform. The proper quantity of chloroform in all cases is the minimum quantity that will produce narcosis, and maintain that state as long as is necessary. This must vary in different cases within wide limits, and just as there are certain people who require large doses of narcotic drugs to produce any hypnotic effect, whilst in others sleep is induced by a considerably smaller dose; so in chloroformisation some people (apart from idiosyncrasy, which is another subject) require large, and others small doses. It is well known that in some adults 15 grains of hydrate of chloral is sufficient to produce a whole night's deep sleep, whilst others require 30 grains, and even that dose repeated once or oftener. Now we know that chloral is converted into chloroform under the influence of the alkaline salts of the blood, and that the sleep produced may be looked upon as merely an early stage of chloroformisation, in which the surface grey matter of the cerebrum is narcotised. An overdose of chloral does not produce symptoms of syncope or indicate a primary cardiac failure. This demands our searching for some other cause for accidents.

A few years ago, I recorded a case of angina pectoris with fatty degeneration of the heart, coronary arteries, dilated aorta and dilated left ventricle, and in whom I had twice given chloroform. A year before for carbuncle of the head, the patient took the drug all right, and without a single bad symptom from start to finish on both occasions, although during one of these administrations he was half an hour under the drug.

As a rule, authors tell us that direct inflation of the lungs is only of use in the resuscitation of new-born

infants, but the condition is somewhat different in them and in aged people to what it is in the normal lungs of middle age adults.

The fluid having been removed from the abdomen in one case, the elimination of chloroform was comparatively easy under the influence of restored function to wider and wider areas of lung tissue.

In this little operation 2½ gallons of ascitic fluid were removed, and this rendered it possible for a proper diagnosis to be made. The tumour consisting of a large irregular mass springing from the left side of the pelvis, with a broad pedicle, and having wide and extensive attachments, both within the pelvic and the peritoneal cavities, it was decided not to attempt its removal.

The removal of the pressure from the vessels of the splanchnic area must have tended to reduce the high blood-tension in the lungs, and increase that in the splanchnic area itself, it thus lessened the chances of asphyxia, and at the same time reduced the distension of the right side of the heart, thus throwing less work on the right ventricle.

Chloroform was administered in the ordinary way, on a cloth cap-shaped like a cone, and as stated, produced no untoward effects for a certain length of time after the commencement of chloroformisation.

In this case there was every reason why the patient should suffer from heart failure (if such a condition is possible), and little reason why efforts for resuscitation should have been successful.

—:O:—

OPHTHALMOLOGY IN OUDH.*

By MD. ABDURRAHIM KHAN BAHADUR, L.M.S.

Assistant Surgeon, King's Hospital, Lucknow.

I DIVIDE nearly 2,700 operations performed on the eye-ball during the last 8 years at the King's Hospital, Lucknow, into (1) operations for cataract; (2) other operations on the eye-ball. But the subject of this paper is operations for cataract.

Examination of eye-ball.—Before dealing with the subject of operation, I would like to state very shortly, some facts about the examination or simple inspection of the eye bearing an important connection between it and the subsequent determination of the nature of operation to be performed and the course of after-treatment to be adopted. In doing this I shall describe facts which, if they escape notice at the time of inspecting the eye, cause failure after operation when everything seems to be going on favorably. The inspection is directed to (A) the appendages of the eye (B) the eye-ball.

(A) *Appendages of the eye.*—(1). Eyelids, (2) eyelashes, (3) puncta lachrymalis. (4) condition of the nasal duct and the nasal passages.

(1) and (2). Any altered appearance of the skin such as loss of thickness and elasticity indicated by hardness, toughness, induration, bead-like swelling, increased curvature of the nasal cartilage, increased vascularity, any undue moisture of the margins with occasional inflamma-

* Read before the Indian Medical Congress and sent to the Board for publication.

secretion, empty eyelashes, together with exudation of sticky secretion or contraction of the palpebral fissure, should always make us suspicious of a good result. A single inverted hair coming out at the time of operation gives any amount of trouble and annoyance after removal of the bandage. The corneal wound will not heal unless the small hair is detected and removed. Gummy secretions of an irritating character have caused sloughing of the eye-ball from the intense inflammation they give rise to after an operation. In such cases an operation for the extraction of cataract, if it is at all to be performed, should be done by an incision on the lower zone of the cornea.

(3) and (4). Any abnormal appearance about the punctum lacrymalis, such as redness of the orifice of the canal, indicated by a raised red spot about the inner end of the margin of the lids, attended with lachrymation either watery or of a slightly purulent character, with a little swelling about the sac, inflammation about the duct, or the nasal passages such as ozæna, or chronic coryza, should always keep us on our guard about the operative interference on the eye-ball. In such cases union of the corneal wound is prevented from irritation produced by the pent-up secretion between the closed lids. Sometimes the secretion finds its way into the anterior chamber, giving rise to suppurative iritis. In elderly subjects on account of the hardening of the tarsal cartilages, the punctum is displaced, and the canal obstructed with a constant flow of tears. In cases like these, the passage should be made free by passing probes for three or four days before operation. Cases with ozæna or chronic coryza can be managed by injecting the nostril with corrosive sublimate lotion and turpentine, and blowing into the cavity some iodoform or iodol. This should be continued regularly, for a few days after operation till the bandage is removed. Syringing of the nostril should be done gently so as not to irritate the eye. It is better to dust a little iodoform or iodol or fine boric acid on the dressing applied to the eye. In this way we manage to operate on cases with ozæna successfully. Cases with chronic inflammation of the sac should never be touched till the canal and the sac are corrected.

B. The Eye Ball.—(1.) *General appearance.*—In the out-door department among the crowd of patients we can tell a great deal about the general condition of the eye by noticing the peculiar attitude of a patient, e.g., an old man with a vacant look, head raised upwards, one hand stretched forwards walking with the help of his stick, is sure to be suffering from total loss of vision either from glaucoma, deep-seated retinal mischief, dense leucoma or disorganization of the eye-ball. While in another, walking with his head downwards trying to utilize the scanty vision at every step he takes, we can fairly conclude that he is suffering from cataract, corneal opacity or granular lids, &c. In the same way a young man with a prominent eye-ball partially closing his eyes every time he looks at a distant object, we are led to suspect myopia. In another patient with slight redness, the pupillary aperture comparatively small, pointed to the nasal side with a little wrinkling of forehead, indicates hypermetropia.

(2.) The movements of the eye-ball give us a fair estimation as to the amount of vision enjoyed by a patient

and the maturity of cataract can be estimated if we hold our hand or finger before a patient's eye and observe the side to side, for we observe that in a patient having a fair amount of vision the eye-balls keep pace with the movement. But in a case of mature cataract, the eye-ball will not move if the hand is kept at a distance of 10 inches to 2 feet. If after the extraction of cataract the eye-ball moves from side to side or from above downwards with the movement of the finger, we know that a fair amount of sight has been obtained.

(3.) *Tension of the eye-ball.* (4.) *Appearance of the Sclerotic.*—Besides the increased tension noticed in glaucoma, we notice a peculiar flabby condition in some eyes, indicating change of consistency of the vitreous. The vitreous in such cases has a great tendency to escape at the least increase of pressure produced either by the speculum or the fixation forceps. Very often when the corneal incision is completed, the lens is ejected with a quantity of vitreous. Great caution is required in manipulating such eyes during operation.

Thinning of the sclerotic indicated by the bulging out of the choroid which presents a bluish-white appearance in patch or patches, is an indication of defective or lost vision. The patient after an operation would always attribute it to something wanting in operation, and not to the morbid condition of his own eye.

Patients coming from out-stations should, as a rule, be allowed to take rest for 24 hours. In some cases, on account of exposure to wind, heat, or particles of dust finding their way into the eye, through want of proper rest during the previous night, anxiety, &c., we notice slight redness in the eye. Such eyes should be washed with boric lotion and treated with atropia before the patients are sent into the eyeward. In some patients, on account of a peculiar idiosyncrasy, we notice symptoms of belladonna poisoning from the small amount of atropia put into the eye. If an operation is performed half an hour after the instillation of atropia, the patient soon after the operation or sometimes on the table, complains of intense thirst, dryness of the mouth, at times he gets delirious and the dressing is disturbed. It is very difficult to keep him at rest, and such cases generally result disastrously. Of late I have been giving a 20 grains' dose of chloral hydrate, the patient after sleeping for four or six hours feels much better. Such an unpleasant mishap can be avoided by keeping the patient under observation for 24 hours before operation.

Operation for cataract.—In performing the operation for the extraction of cataract, our main object is to observe simplicity, avoid unnecessary manipulation of the eye-ball, and finish the operation with as little disturbance of its normal structure as possible. In a good and selected case we require few instruments. A sharp cataract knife, a pair of fixation forceps, a cystotome, a curette and a spring-stop speculum are all that is necessary.

The instruments are soaked in carbolic lotion of 1 in 100. Boric lotion of 5 grains to an ounce is used for the eye.

The eye may be anaesthetized with cocaine, but it is better to commence the operation without it. The cocaine is applied gently, the eye-ball is held by a firm grip

the eye is closed and an assistant is made to hold the patient's head steady. The patient is then placed with the point of the knife with the blade directed towards the anterior chamber. If we omit to do this, it may be pushed afterwards with the pricker. As the operation completes the incision we should be careful not to press the eye-ball with the fixation forceps, as sometimes when our whole attention is directed to the completion of the incision (without giving any jerk to the eye ball,) we quite forget the pressure exerted by the fixation forceps in the left hand. At times this unconscious pressure is enough to rupture the hyaloid membrane and cause the escape of vitreous. The incision completed and the sclerotics pricked either with the point of the knife or the pricker, the speculum is removed. The lens is extracted by a gentle and gradual pressure of the eye-ball at the lower part of the cornea with a curette applied to the outer surface of the lower lid about the margin; the pressure is applied from below upwards. If necessary counter-pressure may be applied a little above the incision by gently pressing the upper lid with the tip of the forceps or by means of a curette applied directly to the eye-ball. Thus by gentle pressure and counter-pressure the lens is made to glide out smoothly. During this part of the operation the patient is told to look downwards. If a portion of the iris during the extraction of the lens is displaced upwards or caught, as it sometimes happens, between the flaps of the wound, it is replaced by means of a curette passed gently into the wound by a light lateral movement. In a good case we should find the pupil quite clear and the vision fairly good to the counting of fingers. Sometimes we find some lenticular matter left behind; it is removed by gentle pressure applied as above described. We should be very particular to syringe out the anterior chamber with boric lotion. The author usually employs a small silver capillary tube about one and a half inches long, one end of which is expanded into a tube of about $\frac{1}{4}$ or $\frac{1}{2}$ of an inch in diameter to which an india-rubber teat or an ordinary india-rubber tubing about two inches thick is attached and fixed by silver wire. The other end of the tube is made airtight by a few turns of silver wire. The lotion is sucked up into the tube and then injected into the anterior chamber in a fine stream which is strong enough to work out any lenticular matter left behind. In syringing the chamber we have another advantage; at times, a portion of the capsule which remains behind the iris is brought into view by the force of the stream. Sometimes the stream can easily suck up this portion of the capsule or lenticular matter into the tube and thus extract it. The operation being finished, the eye-sight is tested by holding the finger before the eye. A drop of astringent solution of 4 grains to the ounce may be put into the eye if necessary.

After protruding the iris, the forceps are used to grasp the iris with the knife with, holding the patient's head. After carefully examining the cornea, when the edge of the pupil is protruding, the point of the pointed straight, gently the knife is applied with the knife for a horizontal incision of the iris, which a piece of iris tissue is kept at the knife with a watch pocket, the edge of the knife is then directed a little upwards and the incision is completed; a crescentic or crescentic piece of iris is then divided, while the rest is the anterior chamber either on the left or right. The length of the pupil. If there is no hemorrhage, the iris is cut at the ends of the iris, it is quite viable; it is easier to be removed with the iris forceps. When there is a little hemorrhage, the anterior chamber is syringed and the entire piece of iris washed out with the lotion. While operating on eyes under cocaine, or when the patient is not anesthetized and does not keep the eye at rest, this way of cutting the iris answers the best. After finishing the operation, the pupil is pricked and the lens extracted as described above. The anterior chamber being washed or syringed, the divided ends of the iris are replaced carefully and gently with a curette or spud into the anterior chamber, and a drop of atropine solution, if necessary, put into the eye. This finishes the operation.

Of the 1,250 cases of cataract extraction which have come under my observation, 610 were performed without iridectomy, yielding 97 per cent and 640 with iridectomy, resulting in 83 per cent of cases with good sight. My practice leads me to conclude that cataract surgery without iridectomy is safe, and that it is possible to operate without iridectomy in at least 80 per cent of cases coming for treatment in our hospital. In determining the question of operative without iridectomy the following points should be carefully noted:—(1) The extent of maturity of the cataract, the size of the lens, the condition of the nucleus and the optical media. (2) If there is any adhesion between the iris and the lens.

The patient is told to adjust the eye as if looking on a near or distant object, or when the eye-ball is closed with the palm of the hand for a minute and then suddenly opened towards the light, the dilated pupil will contract slowly; the lens is generally white, yellowish-white or milky-white, presenting a hyaline or ground glass appearance, at times white dots are noticed on the surface of the lens, in some cases the nucleus is found floating in a bag containing milky fluid, and the radiating striae are seen. In such cases we know that the lens is of small size, there is no adhesion, and the patient quite mature. If iridectomy on such cases is performed, there is every chance of the vitreous escaping. These cases should be selected for operation without iridectomy.

(3). A small eye-ball, a little sunken in the socket, having the characteristic appearance of a hypermetropic eye, the palpebral fissure a little contracted, sometimes the outer angles of the eye on a higher level than the inner, the inner angles appearing as if pointed towards the nasal side, the eye, as a whole, lacking lustre, the pupil more inclined to be contracted but responding freely to the effects of light, the appearance of the lens generally of a bluish-white, grey, brownish-white, or of a dirty brown color presenting radiating striae more visible by throwing light at different angles when the pupil is dilated with atropine. These eyes possess big lenses, probably with some adhesion of the iris. In such cases the incision should be made a little larger, and iridectomy must be performed.

The anterior chamber, after removal of the lens, requires careful examination. It should be washed out thoroughly. Some particles of lenticular matter is generally left behind, even after thorough washing of the anterior chamber. It is in these cases that after removing the bandage, to our great disappointment and annoyance, we find some white swollen lenticular matter occupying a portion of the pupillary aperture which escaped notice at the time of operation. In such cases we should not only perform iridectomy, but be ready to enlarge the incision or even scoop out the lens, if it refuses to move with ordinary pressure.

(3). There are cases of mixed type in which no rule as regards the performance of iridectomy can be laid down. The nature of the operation should be entirely left to the skill, knowledge and taste of the operator. Every case should be treated according to its own special features. A greater number of these cases can be treated by operation without iridectomy.

After care and treatment.—In a case without iridectomy the bandage should be applied with a light but firm and equal pressure on the eye-ball. The patient is generally sent to the ward on a stretcher. He is properly kept on his back undisturbed for 48 hours. He is not allowed to go home after the operation. If there is no discharge, the bandage is not removed till the morning of the sixth day, and on removing the bandage, we note the condition of (1) the conjunctiva, (2) the corneal wound, (3) the pupil, (4) the sight. In good cases there will be:—(1) no discharge or conjunctivitis, (2) the wound fairly united. In some elderly subjects the union of the wound is not

perfect, and then the bandage must be reapplied, the eye retired and clear, (3) vision good.

Should any complication arise, such as conjunctivitis, iritis, or prolapse of the iris, it must be treated on general principles.

In cases where iridectomy is performed, we are not particular to apply any pressure on the bandage on the eye-ball unless there has been an escape of vitreous during the operation. Sometimes we apply a four-tailed bandage of two folds of muslin. The patient is allowed to walk in his bed or we can allow him to go home if he does not like to stay in the hospital, giving necessary instructions as regards rest and dressing. He is allowed to leave the hospital after 48 hours. The eye, if there has been a discharge, is washed without opening the lids after 24 hours and the dressing re-applied. On the morning of the fifth day the eye is opened and examined as above.

In cases with diseases of the secreting apparatus the dressing is changed every morning. The average duration of a patient's stay in the hospital is from 9 to 12 days.

THE CAUSE AND PREVENTION OF CHOLERA.

By E. H. HARRIS, M.A.,

Chemical Examiner and Bacteriologist to the North-West Provinces and Oudh, Fellow of St. John's College, Cambridge.

The causes of Disease.—Everyone must be interested in the methods of preventing those fearful plagues that sometimes occur in India, which bring with them such loss of life, distress, and misery.

At the present time doctors are beginning to understand the nature of these diseases, their causes, and the means of preventing their spread. I intend in the present article to give as simple an explanation of these matters as possible.

The subject is interesting to the people of India from another stand-point, because, as will be seen, many old customs are nothing else than excellent means of preventing the diffusion of disease. Some of these will be mentioned herein, especially in connection with cholera, as the causes of this disease are now best understood.

To discover the nature of disease, before all things, it is necessary to use a microscope. By means of this machine it is possible to see things a thousand times larger than they really are. The hair of the head, when looked at with this machine, seems as large as a tree. By means of the microscope, it is possible to see a whole world of small animals and plants that exist in dirty water, and any one of which is so small as to be invisible to the naked eye, and so small that they cannot be removed by straining through the finest cloth.

If the body of a man dead of cholera is examined, and a small drop of the contents of his intestines is examined with the microscope, it is seen as composed of thousands of a minute living creature, possibly a bacterium, and properties, and which is only to be removed by washing with disinfectants. It is now known that cholera is a living being in the form of a bacterium. It is a very small

Although much is now known as to how the cholera microbe grows, it is difficult to say whether it is a parasite or not. It can move with great rapidity in water, and therefore is like a fish. But it is different from fish, or from any animal, in that it has no mouth. It is to say, it cannot eat solid matter. Its food is first dissolved and then absorbed. They are aquatic and found in well water. Then it often happens that persons using this well will get cholera. It is well known that the symptoms of cholera are like those produced by eating poison, so much is this the case that it has been supposed that cholera is caused by a poison. It has been proved that just as a snake secretes a snake poison, so the cholera microbes when in the body, secrete a poison, and to this poison the symptoms of the disease are due. It is not always that the cholera microbe makes the disease, just as a cow only under certain conditions secretes milk, so only under some unknown conditions the microbes of cholera have the power of secreting their poison and of producing the disease.

The symptoms of the disease do not appear immediately after swallowing the cholera microbe. It needs some time in which to manufacture its poison and to grow and reproduce. Then only does the harvest of symptoms appear, in the same way as the crops do not appear till some time after the seeds have been sown. It is probable that, as a rule, cholera appears three days after the water that causes it has been swallowed.

I have said that these causes of disease are small living beings, in some respects resembling animals, in some respects plants. How do they live? Firstly they need food. Their food is dirt. If they are in water in which is much dirt, the cholera microbes can quickly grow and reproduce. If at this time such water is examined under the microscope, the cholera microbes may be seen in the form of small curved rods. They are so small that if 50 of them are placed in a row end to end, they make a line whose length is equal to the thickness of a hair. If one of these cholera microbes is noticed carefully, it will be seen to grow longer and at length to break into two equal pieces. Each of the minute curved rods thus formed is a cholera microbe. Each again grows longer and in about half an hour will, in turn, break in two and again two daughter microbes will be produced from each individual. Thus it may be understood how these minute creatures, though they have no sex, nor lay eggs, are able to reproduce with great rapidity. If a trace of the cholera microbe is put into suitable water, that is to say, water containing dirt, the microbe may reproduce with such facility that on the following morning the liquid is turbid, because in every drop are many lots of these creatures.

It often happens that the bodies of persons dead of cholera are thrown into the Ganges. Therefore the cholera microbes often get into its water. If this is the case, why is it that no one ever gets cholera by drinking the flowing water of the Ganges or Jamuna? The answer to this question is, that there is no dirt suitable for the cholera microbes in the water of these rivers, except near large towns or at the time of the great annual festival. Consequently, if the cholera microbes get into their water, it is only near the cities or at the festival. If, on the other

hand, the cholera microbes get into the water of a well, it finds much dirt which acts as its food and consequently it quickly grows and reproduces. If the sediment in such a well is examined under the microscope, it is seen to consist of small bits of clothing, small pieces of human skin rubbed from the hands by the dirt, and many other particles of animal origin. If the sediment in the water of the Ganges is examined, no such particles are seen, except possibly at great bathing ghats at times of pilgrimages. On the contrary, the mud that is carried along in the current of the river is seen under the microscope to consist exclusively of small fragments of stones and sand. No particles of animal origin will be discerned, and consequently no food for the cholera microbe is present. The cause of this is manifold. One cause is the purifying influence of air and sunlight, which agencies have the power of destroying every bit of dirt.

The prevention of disease.—It is then probable, from what has been said above, that if the water of wells could be made to resemble that of the Ganges and Jamuna, cholera would greatly decrease. So far as the prevention of dirt is concerned, this can be done by adding to the water various medicines. For instance if a small quantity of alum is added to turbid water and well mixed with it, all the floating particles will be seen to be carried to the bottom and the water will become clear. I have heard of one or two instances in which cholera has ceased after this was done. But I believe that a better medicine for this purpose is potassium permanganate. This is a salt-like substance in whose preparation only acids and mineral substances are employed. It readily dissolves in water, giving it a purple colour. It has such a great power of colouring water that a touch of the medicine is enough to give a pink color to all the water in a well. But the color does not stay permanently. The medicine destroys the dirt that is present, and in doing this is itself destroyed and the color vanishes. If this process is observed in a glass, after sometime a brown sediment will be seen to appear. This sediment consists of the medicine combined with the dirt that may have been present floating in the water. Thus though no change is seen at this time be visible in the water, there is this difference, that before the addition of the medicine there was some unclean substance dissolved in the water, but after the addition of the medicine there is no dirt present in the water. Both this and the medicine will have sunk to the bottom.

In order to cleanse a well with this substance, it is necessary to add enough of the medicine to give a faint pink color to the water. For an ordinary well this will be one or two ounces. The permanganate should be added at sunset, in order that the water may be left undisturbed as long as possible. In this way the sediment will have more time to settle to the bottom. On the following morning, the water will be fit to drink. If a faint red colour still persists this day after sunset, or the substance is not potassium when that day comes, the water is not pure and the person who objects to take it should be the health of those persons it will be better to take the water out of the well until all color has disappeared.

the cholera microbe is not so easily killed as it is often supposed to be. The cholera microbe is not so easily killed as it is often supposed to be.

There is a popular belief, however, that the cholera microbe is not so easily killed as it is often supposed to be. The cholera microbe is not so easily killed as it is often supposed to be. The cholera microbe is not so easily killed as it is often supposed to be.

Prevention is better than cure. It is better to prevent the cholera microbe from getting into well water than to try to prevent its doing harm when it once gets there, by removing its food. In order to prevent the cholera microbe from getting into the wells, I can suggest no better remedy than certain customs that already exist in India, and which, if they were more generally observed, would undoubtedly have a more beneficial influence than is the case at present.

Firstly, it is now well known and proved that the cause of cholera is often carried from place to place by travellers. It is now known that the cholera microbe lives for the most part in water, and there is no doubt that travellers bring the disease into a place by putting the cholera microbe into the well water of the places to which they come. This they probably do by means of the *dols* or *lotes* that they carry with them. For instance, a short time ago I had to investigate a cholera outbreak in a hospital for English troops in Lucknow. It was found out that a few days before cholera appeared in the hospital, a Hindu had come into residence in a neighbouring compound. The best well in the place was used for drinking purposes, and there can be little doubt that the Hindu went to this well to get his drinking water. Two days after his arrival, he was attacked with diarrhoea, which some time later developed into cholera. With little doubt the Hindu had become infected with the microbe of cholera during his arrival in that place. Then he became ill and fell into the well. After this, cholera appeared among the patients in the hospital, who drank water from the same well.

In some districts during the hot weather, a hired Brahmin with a *dol* and rope is stationed by the side of the well for the use of travellers. By thus preventing the travellers from using their own *dol* or rope, they greatly lessen the chances of the well becoming infected with the cholera microbe. In other districts I believe it is customary for the villagers to keep persons on the high road who draw water and give it to travellers. These customs appear to me to be most excellent, and tending greatly to prevent travellers from carrying cholera from place to place. Another custom that appears to me to be of great value, when the infective material is present in a village, is that of not allowing any cattle or horses to come near a well containing drinking water. Such persons fear that the animals will come into contact with dirty water, and so they try to prevent the cholera microbe from getting into the well by keeping the animals away from the well.

For the same reason, it is better to prevent the cholera microbe from getting into well water than to try to prevent its doing harm when it once gets there, by removing its food. In order to prevent the cholera microbe from getting into the wells, I can suggest no better remedy than certain customs that already exist in India, and which, if they were more generally observed, would undoubtedly have a more beneficial influence than is the case at present.

Secondly, it is now well known and proved that the cause of cholera is often carried from place to place by travellers. It is now known that the cholera microbe lives for the most part in water, and there is no doubt that travellers bring the disease into a place by putting the cholera microbe into the well water of the places to which they come. This they probably do by means of the *dols* or *lotes* that they carry with them. For instance, a short time ago I had to investigate a cholera outbreak in a hospital for English troops in Lucknow. It was found out that a few days before cholera appeared in the hospital, a Hindu had come into residence in a neighbouring compound. The best well in the place was used for drinking purposes, and there can be little doubt that the Hindu went to this well to get his drinking water. Two days after his arrival, he was attacked with diarrhoea, which some time later developed into cholera. With little doubt the Hindu had become infected with the microbe of cholera during his arrival in that place. Then he became ill and fell into the well. After this, cholera appeared among the patients in the hospital, who drank water from the same well.

Thirdly, it is now well known and proved that the cause of cholera is often carried from place to place by travellers. It is now known that the cholera microbe lives for the most part in water, and there is no doubt that travellers bring the disease into a place by putting the cholera microbe into the well water of the places to which they come. This they probably do by means of the *dols* or *lotes* that they carry with them. For instance, a short time ago I had to investigate a cholera outbreak in a hospital for English troops in Lucknow. It was found out that a few days before cholera appeared in the hospital, a Hindu had come into residence in a neighbouring compound. The best well in the place was used for drinking purposes, and there can be little doubt that the Hindu went to this well to get his drinking water. Two days after his arrival, he was attacked with diarrhoea, which some time later developed into cholera. With little doubt the Hindu had become infected with the microbe of cholera during his arrival in that place. Then he became ill and fell into the well. After this, cholera appeared among the patients in the hospital, who drank water from the same well.

If these rules were observed with exactness, it is difficult to see how cholera could spread from place to place. It ought to be possible to observe such rules because they are founded on customs that have existed in India from ancient times, and are little more than an appeal for the more strict observance of rules that already exist, and which are shown to be rational by the description of the nature of the causes of cholera at the commencement of this paper.

How does a native of India give water to another to drink? He first draws water in a *dol*, then he takes the water from the *dol* in a *lot*, and pours it into the up-turned hands of the man who wants a drink. If you ask him why he does not pour the water direct from the *dol* into the man's hands, he will reply that he is afraid that some of the water might splash back from the man's hand on to his *dol* and thus lead to a pollution of the water. What is meant by this "pollution"? If the hands of the man who receives the water were washed in the strongest poison known, is it possible that the smallest drops that might splash back on to the outside of the *dol* could be harmful to the water that was in the *dol*? I am sure that no such poison is known. If this is so, it is to be feared that the good custom of the natives is not to be followed. The good custom of the natives is not to be followed. The good custom of the natives is not to be followed.

persons but which bring along with them many millions of germs of cholera, and which are so small that the smallest drop of water may contain many thousands of them. Thus the drop of water that might splash from the man's hands on to the *dol* might be enough to infect the whole water in the well and thus cause cholera. Just as the "germs" or "germs" weighing only a part of a tola may cause the change of many seers of milk into *doh*, so a mere trace of the cholera microbe that might get into a well from a defiled *dol* might cause the change of all the water that the well contains into a liquid capable of giving cholera to every one that drinks it in sufficient quantity.

Thus this custom appears to me to be good, but it might be more valuable if it were more carefully observed. I know that some care is taken that the iron *dol* in which water is drawn should be used for nothing else, and Muslim *dhokees* do not allow other people than themselves to touch their *mussacks*, but further care should be taken that such utensils are preserved from pollution. I have seen women going to a well carrying a *ghurra* on their heads and a *dol* in their hands and taking no care that the *dol* should not touch their *langha* which probably was far from clean. Further, it sometimes happens that the *shabutra* of a well, and the ground that surrounds it are dirty, and I doubt whether sufficient care is taken in not placing the *dol* on such dirty places.

Owing to the purposes to which they are put, the *lotah* is far more likely than the *dol* to infect a well. Sometimes in villages these vessels are not lowered into wells used for drinking purposes. At *melas*, on the other hand, I have often seen both *dols* and *lotahs* being lowered into wells at the same time. Much good would be done if this could be prevented, and if Brahmins could be employed to draw water for pilgrims for all purposes, or if a tank with a tap, from which *lotahs* could be filled, could be placed near every well.

In order to prevent cholera, the Government are employing certain new methods which have hitherto been unknown in Hindustan. Especially to be mentioned is the introduction of pipe water into the larger towns. Often the nature of this water is completely misunderstood by the inhabitants. In Agra, for instance, some persons tell me that they cannot drink this water because it is hot; others tell me that they cannot drink it because it is cold; others because it comes out of a pipe that has been used by persons of lower caste. I have quoted our recent knowledge of the nature of disease to show that many of the existing customs are good. I can quote the same knowledge to show that the above objections are bad. The pipe water is water that has been carefully filtered with much trouble and care in order to remove from it the minute living germs that are the causes of disease. The process of purification is too complicated to explain here, but it may be stated that the sand that is used to filter it is washed by machinery in order to avoid contact with human beings by which it might possibly be defiled. Thus even a pipe with side water, that pipe water always contains far fewer of the minute living beings above described than the water of the *dhokees* or *Jaams*, and thus is better than any that can be obtained in India, so far as

the question of disease is concerned. I have above explained why it is good to object to water from the hands of a man of low caste splashing on to the outside of a *dol*, but I can find no equally good reason for objecting to such water splashing on to the outside of the pipe of a stand-post. In the first case, each splashing is dangerous because the *dol* will be lowered into the well and will possibly infect the water-supply. In the second case I fail to see how drops of impure water on the outside of the pipe could possibly infect the water flowing through it, at any rate, if care be taken that the vessels in which the water is taken away, are not allowed to touch the pipe.

But the neighbourhood of a stand-post should be kept clean, as when the water is not flowing, there is the possibility of dirt being sucked back into the pipe.

In some villages Government are introducing pumps attached to wells. If the walls of a well are good and in good repair, there is no doubt that all substances that can get into the water must come in from above by means of the vessels lowered into the well. Consequently, if the well is covered in, and if water is only raised by a pump, no harmful substances can get into the well, since water only flows in one direction through the pipe of a pump. Pumps for this purpose are now being brought into India, which, like the large pumps in the water-works, contain no leather in their valves, and I feel confident that if it turns out to be possible to introduce them into villages, much benefit to the inhabitants will result.

I have referred to many customs in this paper which, if they were more closely observed, would be of great use in checking the spread of cholera. Though educated persons may be able and willing to adopt these suggestions, it is probable that uneducated persons cannot easily be influenced in this way. But I feel sure that educated natives who read this brochure will be able to see, from their knowledge of the natives of India (which is greater than mine), how far these suggestions are practicable, and such persons are likely to do good if they exert their influence to a greater extent than they do at present to ensure the purity of the water-supply, or if they cleanse the wells with medicine as above described, if they have become infected. I have not attempted to include in this book certain other measures that without any doubt would be of great use in order to prevent the spread of cholera. For instance, since these minute living organisms that cause diseases are destroyed by boiling, safety in a cholera epidemic can be obtained by drinking only boiled water and food that has recently been cooked or warmed. But this for many poor people must be practically impossible owing to the difficulty of obtaining fuel. Neither do my remarks cover the whole of the ways in which cholera may be brought on. Since the cholera microbe is destroyed by drying, there is no doubt that the disease is never caught by inhaling air. It is a disease whose cause is always in the substance eaten or drunk. Generally the disease is contracted by drinking water that contains the infective material. Sometimes however, it is contracted by eating infected food. This is likely to happen in dirty places where there are bad smells and many flies. The cholera microbe is always present in quantities in the stools of persons suffering from the disease. It is now known that flies settling on these stools may carry the disease germs from place to place and deposit them as food and thus the cause of this terrible malady may get into the system and cause the disease.

THE CLIMATE OF NEW SOUTH WALES.

By J. ABERNATHY THOMSON, M.B., D.P.H.,

*Chief Medical Inspector of the Board of Health,
New South Wales.*

Persons who have never visited Australia, sometimes ask what sort of climate it has. A fair answer would be "All sorts;" for they forget that it is a continent which measures nearly three million square miles. It lies between the 11th and the 39th parallels of south latitude, and between the 118th and 153rd meridians of east longitude.

Wide differences, mainly of temperature, are indicated by the number of degrees of latitude through which Australia extends; roughly speaking, its northern third lies within the tropics, its southern two-thirds outside them. The meridians of longitude serve to measure differences of another kind. In the southern hemisphere rain comes from the east, consequently the eastern coastline which borders the colonies from north to south, of Queensland, New South Wales, and Victoria is the fertile portion of Australia. The rainfall is greatest there, and diminishes farther and farther towards the west; rapidly at first, more gradually as the western plains are traversed.

I wish to speak now of a portion only of this vast territory—of the climate possessed by New South Wales. A slight description of the physical features of this province will make it easier to understand the favorable varieties of climate which exist, even within the bounds of this limited portion of Australia. New South Wales lies between the 29th and the 36th parallels of south latitude, and the 153rd and the 141st meridians east of Greenwich. It has a coast-line to the Pacific of about 700 miles. It is naturally divided into three zones by the dividing range which runs north and south parallel with the coast, and at a distance from it, which is sometimes as much as a hundred miles. This sea-ward belt of country is called the coast-zone, and it has an area of 38,000 square miles. Narrow valleys and deep gorges lead up the eastern face of the dividing range to the tableland zone, which stands at an average elevation of 3,000 feet above the sea; it is about a hundred miles wide, and measures 65,000 square miles. Gentle slopes conduct from it to the great plains of the western interior, which have an area of 188,000 square miles. It will now be plain, that the climate of New South Wales must be spoken of in relation to these three zones primarily, and with subsidiary reference to latitude.

The following details of temperature and rainfall have been taken from accounts published by the Government Astronomer (Mr. H. C. RUSSELL, C.M.G., F.R.S.). The climate of the coastal zone is milder than that of corresponding latitudes in the northern hemisphere, and the range of temperature is not great. Thus, at the northern extremity of this zone (E. lat. 29°) the climate, as inferred from latitude, should resemble that of Delhi, or on the Gulf of Suez; yet in fact the mean temperature there is but 67°-5, or only 1°-7 above that of Meadna, a spot 2° farther from the equator. Similarly, at the southern extremity of the coastal zone the mean temperature might be expected to be much above 60°-2, which is what it actually enjoys, and which is practically the same as that

of Rome, a city placed 42° miles farther from the equator. As also at Sydney, the capital (population 300,000), which is seated on the coast of south latitude 34°-35°, the mean temperature is 63°-9, or about the same as that of Florence and Toulon. The mean summer temperature being slightly under 71°, that of winter 54°. And this comparison brings out a most important point for those who would choose their climate—namely, the unusually small range of 17° only. The extremes must also be mentioned. The greatest summer heat ever experienced in Sydney was 106°-7, the lowest winter temperature 25°-9; but it must be pointed out that while these extremes are very seldom indeed so much as approached and frost (even according to the extreme for 33 years or continuous observation) is unknown, the heat of summer seldom exceeds 90°, and is found disagreeable by Europeans on account of moisture of the atmosphere only for two or three days at a time about in the middle of summer.

On the tableland zone the yearly average temperature is barely 56°; the mean summer temperature only reaches 69°, that of winter 45°-9. At that elevation and distance from the sea the range is naturally greater, though still low; frosts are common in winter, and snow sometimes falls. Thus, even in summer, the coast-zone dweller can by a few hour's railway travel get a bracing change, and in winter as low a temperature as he is likely to find agreeable, accompanied though it generally is by sunshine and a transparent atmosphere.

As to rainfall, the yearly mean at Sydney (33 years) was 49 inches, which fell on 151 days; while on the tableland it averaged 81 inches. At Sydney the average annual evaporation calculated on the same period was 38, and it varied between one and a half during the winter months of June, and five and a quarter during the summer months of December and January. On the whole, the climate may be described as one of the most equable; yet it is also one of the most agreeable, for, as has been shown, appropriate seasonal changes occur.

Probably these facts, which result from Mr. RUSSELL's long-continued and well-known observations, do not convey to the unversed reader any very distinct impression of the conditions of life actually met with in New South Wales, and at last that special point, the capital. But it is necessary to furnish a check on expressions of personal sensation, and the more that terms which cannot but be brought to verge on the enthusiastic must be employed by any writer competent to describe them. Without venturing on that ground, some sober facts can still be adduced by way of useful practical illustrations. Briefly, the climate of the coast-zone invites to open-air life all the year round; neither the heat of summer nor the cold of winter interferes with athletic sports, or shooting, or fishing, or yachting—shall it be added here, or with more serious occupations? Europeans at Sydney were the ones they have been accustomed to in their own more changeable and colder climates. In summer the lighter kinds of cloth are chosen, of course, and waistcoats may be omitted; yet as an ornament displayed by one comes only. On the other hand, during the winter months a great deal of the same garment is worn; it is seldom really required except in storm, or for the frosts,

...at night. But the traveller who... during the winter needs heavy... for use by night during five or six... of the year. So that many are dwelling on the coast... exhausted by the moderate heats of summer, he can in a couple of hours reach an altitude of 4,000 feet, and a temperature in which blankets at night are a necessity. Fogs are scarcely known anywhere; and though the sky is not constantly blue—which would be a phenomenon even more fatiguing in the long run than constant clouds—yet the atmosphere is such that all shadows are transparent, and the color of distant objects can be distinguished as far away almost as their forms are visible.

The happiest combination of all that is best in warm and in cool climates, prevails in New South Wales. There is a spot among mountains where Norwegian settlers exercise perforce on national snow-shoes during four months of the year. Elsewhere, and there alone in Australia, do the pure skies and golden light of the tropics concur with an invigorating air; there alone do the orange and the hardier fruits of northern Europe flourish almost within sight of each other. Spontaneously in that brilliant environment the mind turns to all that is associated in art and song, and games with classic Greece.

—:—

ANOTHER DAY WITH PROFESSOR HAFKINE.

By ALF. MCCABE-DALLAS, L.M. Dub., L.R.C.P. &c.

Kumbhur.

CONTINUING the subject of inoculation against cholera by DR. HAFKINE, who recently returned and repeated the second or final process on those whom he operated before, I described how the solution was prepared in the first instance, but omitted to mention that the microbe having been deported from Saigon in French China to Paris, was cultured in the Pasteur Institute, brought from thence to India by HAFKINE, and the supply maintained by the tube-to-tube development on agar-agar. On the present occasion in Cachar, the comma was secured from the soiled cloth stained by the intestinal evacuation of a patient who had died from the disease. Scraping off a portion, it was put under the same high power microscope to be recognised and separated from any other germs which may be in the field. It was then transferred under every bacterial care to a tube of agar, where after multiplying itself most prolifically, was suspended in sterilised water and injected into the peritoneum of an adult guinea-pig by a straight needle Hypodermic syringe. No incision was made to reach the part, as HAFKINE by manipulating the animal's abdomen with his fingers was able to recognise the object required. The intestine was not pierced. The danger of a straight needle is that the animal in its struggle is likely to have its bowel wounded, and this has to be avoided. Dr. BACON has invented a curved needle which, being placed at the point, has its eye in the middle, time in passing the gutters; the needle can be pushed out in a curve and withdrawn after the fluid has been injected, without any fear of injury to the intestine.

The strength of the comma is measured according to the time the guinea-pig takes to die, and the course of death

is, so short, due to the influence of the generated poison on the sympathetic nervous system, there not being any trace of cholera indolence during life, except a perceptible fall in temperature. It invariably necessitates four guinea-pigs being inoculated to attain the requisite degree of intensity unless the second or third die within the prescribed time of eight hours. This is about the limit fixed, and usually the first pig expires in 26 hours, the second in 15, the third in 12, and the fourth in 8 hours—the lowest level at which death can be obtained under ordinary circumstances—but in some peculiar cases of idiosyncrasy it might occur earlier, or not at all. The animal appears to experience no inconvenience of completion of the injection, as it moves around quite freely and eats, neither any symptoms indicative of suffering, and death seems too vertice it in a very quiet manner. On the expiration of 24 hours *post-mortem* is performed, and the contents of the peritoneal cavity abstracted, in the form of a pinkish opaque fluid, which is literally swarming with cholera microbes. The contents of the bowels, which have assumed a liquid condition, are left undisturbed as nutrient material, free from the comma. The microscope is set to work again, the microbes transferred to tubes, and the resultant matter eventually shaken up in sterilised water, is injected into the individual in the same way and quantity as the first inoculation; the same kind of pain and fever following. Protective influence is now supposed to exist for seven years; but, like small-pox, cholera may attack in a modified or mild state. The second inoculation therefore differs from the first in the culture being maintained from tube to guinea-pig and *vice versa*, instead of merely from tube-to-tube, although in both methods an original microbe from actual cases of cholera was used. In refusing to do the second inoculation without having done the first the reason is not because of risk in producing cholera, but the seat of an injection is likely to terminate in a large slough. The measurements of a comma bacillus are: length $\frac{1}{1000}$, diameter $\frac{1}{1000}$ of an inch, hence it would need 75,000 to cover a square inch of surface, and what the number might be to occupy a cubic inch of space would easily startle the most sceptical imagination!

There are conditions under which the comma is rendered sterile for the time being, and which disturbs and affects its natural habit in propagating its species for no other purpose apparently than that of committing mischief on mankind, for instance, it ceases to exist in the presence of an excess of oxygen, also carbonic acid; soda water obtained from a reliable source and retained a few days before use is, owing to the gas of the latter and pressure combined, deemed sufficient to destroy its life, if by any means it found its way into a bottle. Pressure of a hundred atmospheres has the same effect in a short time, although the immediate result is merely to suspend its potential functions. Stagnant pools and drains, low muddy bedded rivers, dark wooded walls, and exclusion from light, are places it revels in, while mountain streams, springs, and rivers with gravel or rocky beds, are localities it scrupulously endeavours to avoid, and more so in ratio to the rapidity of the current. Nitric acid keeps him in a latent state and prevents culturing in such media, while the phosgene, or carbolic acid, are the most deadly enemy.

It is hoped the promoters of this new discovery will be able to give more definite demonstrations in explaining the physiological value of its effect on the system to secure public confidence, and that its end will not terminate as K.M.'s tuberculosis is being converted into a sort of antitoxin through the medium of a horse. Naturally experiments are essential to prove facts, but when, as for cholera, they have to be performed twice over, it causes the natives, for whose benefit these performances are doubtless being carried on, to exhibit a certain amount of scepticism, unfortunately for the benefit of this scientific undertaking. Cholera has suppressed itself so far that no comparison can be made, which must be attributed to the extra precautions in the sanitary line adopted on estates, where the drains have been deepened and properly sloped, wells cuplied, cleaned, and lime and permanganate of potash put in every mouth alternately, more light and ventilation insisted on and less crowding in huts, and wholesome water supplied to field workers, instead of allowing them to drink from unknown sources.

A MIRROR OF PRACTICE.

HEPATIC ABSCESS FOLLOWING ULCER OF DUODENUM CAUSED BY A BURN.

By SURGEON-CAPTAIN PATRICK HEHR, M.D.,
F.R.S.E., F.R.C.S.E., D.P.H. (Cantab.)

*Lecturer on Pathology and Clinical Medicine,
His Highness the Nizam's Medical
School, Hyderabad.*

On the 4th April 1894, Mr. U. R., of the Regular Troops, sustained a very severe burn by the explosion of a kerosine oil lamp, the burning oil falling on various parts of the body and igniting the clothes which burned until they were extinguished. The chief parts affected were: (1) Face, scalp, and front of neck. (2) Trunk, especially the middle line anteriorly, extending on the right side from the clavicle to the 9th rib, and on the left over the area corresponding with the anterior part of the left hypochondrium. Small patches of the right lumbar, iliac and the hypogastric regions were also involved. In addition to these both forearms and hands were covered with several large blisters, the back of the hand being involved to the depth of the true skin, which was greatly charred on its posterior aspect. The left leg, foot and toes were also affected.

The patient was seen within 20 minutes of the occurrence, and was found in a semi-collapsed state. Morphine and atropine were at once injected hypodermically, and the burned surface covered with caron oil. On the 9th day after the accident the patient complained of a pain over the epigastric region, which gradually extended till it occupied the whole of the anterior part of the abdomen above the umbilicus. Pressure increased it, especially in the epigastrium, as did also coughing, deep breathing, or lying on either side. There was fullness of the liver, but no actual hypertrophy, and no pain on pressure.

On the 10th day after the accident vomiting set in, and after continuing for 24 hours, became somewhat bloody. On the 12th day diarrhoea began, the motions at first of

semi-liquid consistency, becoming whitish and watery, and on the 16th day the dejecta contained blood and mucus intimately mixed with faecal matter, but none of the ordinary symptoms of dysentery were present. There were about 10 motions a day.

On the 21st day he had very severe hæmorrhage, which was checked by the use of cold externally, ergot, hæmeline and turpentine internally. From this time onwards the patient seemed to recover without another bad symptom, and on the 35th day after the explosion returned to duty, and continued to work for 18 days. He was then attacked with acute croupous pneumonia, which ran the ordinary course of that disease, but after the crisis he did not appear to convalesce as satisfactorily as one would wish. The cough continued, he had diffused pain over the whole of the base of the right lung anteriorly and posteriorly, and there was a perceptible bulging below the lower angle of the right scapula. Nor did the inflammatory deposit of the right lung clear up—bronchovesicular, respiration and bronchophony continued, and there was dulness. This was his condition on the 27th June, exactly a month from the beginning of the pneumonia. Thinking that there was some fluid in the pleural cavity, we inserted an exploring hypodermic syringe, with which we drew off 6 ounces of inflammatory fluid. This gave no relief. The temperature was constantly over 100°F. in the morning, and 101.5° or thereabouts in the evening. He was almost constantly in a profuse sweat. This was manifest chiefly at night, and aroused our suspicion as to the possibility of suppuration in the liver. Four days after the aspiration of the chest he had severe and prolonged rigors in the afternoon, and another about 11 P.M.; the temperature rose to 104.6 at 5.30 P.M., and subsided to 100.5 at 9 P.M., and again at 2 A.M. was 103°, whilst at 8.30 A.M. the following day (10th July) it was 99.5 F. Between each rigor there was profuse perspiration. He now first began to complain of severe pain over the liver and lower border of the chest walls posteriorly. Whilst the lower edge of the liver could be distinctly felt anteriorly, especially during inspiration. There was manifestly no very great enlargement, the dulness not going beyond the fifth rib anteriorly. These symptoms continued for another week, when the liver began to increase considerably in size, the cough became more severe, dyspnoea set in, and severe vomiting occurred during each exacerbation of temperature. I entertained no doubt but that there was pus in the liver, and as this organ increased in size, my conviction to that effect became more absolute. We proposed an exploratory operation, but the relations were averse to this, stating that it was only after I had operated on the chest that the patient got so much worse. After a few explanations they consented. We used the same instrument, a diagnostic Dieselofoy, but with the ill-luck that seemed to pursue the case from the beginning, I just failed to hit off the abscess cavity, which was about 3½ inches from the surface—the needle being too short—could not reach it. They would not allow me to make another attempt, though the patient appeared to be a little better for a few days, but then began to suffer very severely, and could not get relief from pain in any position, either day or night. His proffered being

...the necessity of an exploratory operation, and they...
...the relief experienced each time, the patient's general
condition retrograded, nausea or actual vomiting was
rarely absent for a whole day together, colliquative
sweats continued, even in the absence of fever and rigors.
These latter however appeared again a week after the
second aspiration, and three days later on, a watery diarrhoea
set in, with from ten to twelve motions a day, and with
each accession of temperature he appeared to get worse.
He became delirious and noisy, and began to show other
signs of nervous prostration—*fascicatio* and *substitus
tendinum*, a dry and crusted tongue, scordes about the lips
and teeth, coma vigil, &c. Whilst these grave symptoms
were developing, a red oedematous swelling appeared
near the right infra-scapular region, dulness on percus-
sion extending to the level of the spine of the scapula, all
breath sounds, bronchophony and vocal fremitus had dis-
appeared, but anteriorly subcrepitan rales were audible to
the level of the 2nd rib, up to which there was absolute
dulness on percussion also. The breathing was now 56
per minute, and the pulse 135. A medium-sized trocar
and canula was inserted in the 5th interspace just below
the posterior axillary fold, and 27 ounces of sero-purulent
fluid were removed. This verifying again the diagnosis of a
coincident empysema. Although the dyspnoea became less
urgent, and the breathing was reduced to 48 per minute,
the patient grew worse and sank from exhaustion on the
7th September 1894, five months prior to date of post-
mortem.

Pathology.—We found practically the whole of the
lower half of the duodenum in a state of patchy con-
gestion, with five healed and two healing ulcers. The
largest was about the size of a shilling, and the smallest
half an inch in diameter. In one place three ulcers
had run into one another, and the former ulcers were
represented by a grayish depression with an uneven
base but well-defined borders. The whole of the pyloric
end of the stomach was thickened, soft, and congested,
and just above the upper semi-circumference was a rough
orange surface, with rough hard edges. The remainder
of the stomach canal was normal to the naked eye.
The peritoneum over the whole of the liver was much
thickened, as was also the folds of the lesser omentum,
which were covered with thick layers of puriform lymph.
The spleen was enlarged to about three times its normal size,
and its surface was much thickened and covered with
lymph. The peritoneal cavity contained 11 ounces of an
opaque, sticky, whitish fluid, thick with inflammatory
material. The lungs were considerably displaced upward
and to the right, and were hyperinflated and matted,
especially the left lung. The right lung was collapsed to

one-third its normal size, and covered with a thin
layer with a layer of puriform lymph, which in one part
of the lung was about 4 or 5 mm. thick, and in some
places it required considerable force to push the lymph
through it. Another patch posteriorly, about the middle
of the rounded surface, was also covered with a thin but
soft and ragged lymph which could not be peeled off.
The whole of the lung was congested, and the lower
lobe and greater part of the middle lobe had the appear-
ance of purulent infiltration.

The liver itself was considerably enlarged, and adherent
throughout its upper and posterior surfaces to the dia-
phragm, and could not be separated from the chest without
laceration. At one point, corresponding with a fissure in the per-
pendicular one inch behind the anterior surface, the
diaphragm was partially eaten into by the advancing sup-
puration. The right lobe was occupied by three abscesses,
the largest (the one aspirated) was 2 1/2 inches in diameter, and
separated, and was about the size of an 8 months' foetal head.
Another, anterior to, and below this, was about the size of a
lawn tennis ball, and the third, inside the smaller one,
about the size of an almond. The left lobe also contained
three abscesses in close juxtaposition to one another; the
largest was about the size of a large walnut. Surrounding
each of these abscesses, however, were a large number
of small white patches, which were in reality points of
suppuration about to coalesce with the larger ones. The
abscess walls and *tout ensemble* of the liver were quite
unlike the form of an abscess with which we are here
familiar—the ordinary tropical abscess. The pus micro-
scopically contained neither *staphylococci*, *streptococci*,
nor *amceb coli*. There were, however, crowds of ordinary
small micrococci, and a number of small bacilli with
rounded ends, which stained after Gram's method, and
presented a beaded appearance, never more than three
bright spots however, being seen in the body of any one
bacillus. It was smaller than the bacillus typhosus, and
gave one the idea of its being the bacillus *commensalis coli*.

This was an exceedingly interesting case from start
to finish, not only because of its rarity, but because the
clinical phenomena corresponded precisely with what
we should have expected.

AN INTERESTING CASE OF OBSTRUCTION OF THE BOWELS

(UNDER THE CARE OF BRIG. SURGEON, LIGHT COL.,
JAMES ARNOLD, M.D., I.M.S.)

Physician in charge of St. George's Hospital, Bombay.
(REPORTED BY ASST. SURGEON, A. V. M. KING.)

A PATIENT, named L. I., was sent into hospital from the
neighbourhood of Bombay by his medical adviser on
the 5th January 1895, suffering from symptoms said
to be due to obstruction of the bowels (dysenteria)
of probably eight days' duration. A letter from the
medical attendant described symptoms of constipation,
with severe abdominal pain, which were not relieved
by purgatives, or by opium, belladonna or other remedies.

History.—Patient says, that about 12 days ago, he
felt the first pain in the right side of the abdomen,
which he considered trivial, and took no notice of.

about 14 inches in length, and was passed in the morning. The patient was much excited and the pain above alluded to increased in severity. To relieve these symptoms he took half a bottle full of castor oil, but this only aggravated his condition. He states that he had been exposed to a chill, when was, after being wetted. A medical gentleman was called in consultation, and various remedies were resorted to, with the exception he passed small quantities of feculent matter in soft stools, which the doctor believed came from the lower bowel. Hiccough and vomiting having supervened, an operation was thought to be imperative; he was accordingly advised to go into hospital.

Condition on admission.—Patient much emaciated, with a care-worn expression, pinched features, cold and clammy extremities; tongue thickly furred, brown and dry, great thirst, constant hiccough and vomiting, temperature 101°F; pulse 120, weak and irregular; respiration 28, short, hurried and difficult.

On inspection, the abdomen was found to be much distended and tympanitic, especially toward the right side, where a tumour, tympanitic on percussion, somewhat larger than a man's fist, could be seen and felt in the neighbourhood of the ileo-caecal valve, and extending up along the line of the ascending colon; this was exceedingly painful on pressure. He lay with his legs flexed, and any movement seemed to cause him excruciating pain.

Diagnosis uncertain. Probably typhilitis or enteritis; possibly obstruction.

Prognosis grave.

Symptoms.—7th January 1895.—Pain is somewhat less severe; tumour less resisting; bowels moved freely, six times in the 24 hours; stools loose, yellowish grey, offensive; great thirst, constant retching, occasional hiccough; tongue still furred; takes nourishment very well; passed a very restless night; perspired profusely.

8th January.—Tumour softer, and patient can now bear a fair amount of pressure over the affected area. Tongue clean and moist; breath extremely foul; had 13 stools, 7 of which were passed during the night, preventing his having any rest; perspired profusely.

11th January.—Extremities more cold and clammy; abdomen is more distended and tympanitic, but the tumour has considerably decreased and is softer to the touch; pain felt only on deep pressure; passed 11 stools in the 24 hours, of the same character.

12th January.—Extremities continue to keep cold and clammy; no retching or hiccough since yesterday; had a number of stools, and during the night passed a very large piece of intestinal mucous membrane 36 inches in length and about 2 inches in diameter. The tumour has completely disappeared; there being only some induration felt in the arch of the right iliac region; night passed in agony.

13th January.—Pain, slight on deep pressure; had 4 stools in the 24 hours, one contained about 2 inches of a membranous clough; appetite is very fair; had a good night's rest.

14th January.—Passed 4 stools, loose, yellowish, and offensive. Two stools contained membranous cloughs,

about 14 inches in length, and were passed in the morning.

15th January.—Passed 4 stools, one containing a membranous clough about the size of a man's fist, and another containing a piece of intestine about the size of a man's fist, and another containing a piece of intestine about the size of a man's fist, and another containing a piece of intestine about the size of a man's fist.

16th January.—Passed 2 stools, one of a pale brown color; no cloughs; he is getting on, and is now allowed to sit up in bed.

21st January.—Passed 2 stools in the 24 hours, one solid, yellowish brown; tongue clean; appetite very good; is allowed to get about.

22nd January.—Is now perfectly convalescent.

25th January.—Discharged cured.

Treatment.—Pulv. ipecac 30 grains in the morning, 10 grains every evening; calomel, opium and quinine in pills for the first three days. Lette acid carbolio 1—40 compress over the right iliac region. Pulv. Opia at Greta preparata was also administered to check the diarrhoea.

Diet was chiefly warm milk with barley water as a drink, latterly chicken broth, arrowroot congee, milk, biscuits, blanc-mange and calves foot jelly.

Remarks by Brigade-Surgeon Lieut-Colonel James Arnott, M.D., Bombay.—The symptoms in this case on admission were severe, and with a history of constipation for eight days, in which treatment had failed, with vomiting hiccough, a rapid pulse, pyrexia, and a very haggard face; it seemed possible there was intestinal obstruction. The abdomen was distended, hard, and extremely painful, but there was so much increased swelling in the neighbourhood of the caecum, that it occurred to me that it must be a case originating in inflammation there, a sort of anomalous typhilitis or enteritis, that I decided not to adopt any operative procedure, but to treat for typhilitis. Accordingly, the above-described treatment was ordered and local counter-irritation by compress applied. Under this treatment a rapid improvement occurred, and in a few days the patient appeared out of danger. On 12th January (a week after admission) a membrane, 3 feet in length, was passed, and I append a description of it by Surgeon-Captain CHILDE, M.B. (Lond.), L.M.S., Professor of Pathology, Grant Medical College:—

"The specimen is a hollow tube, and has an elastic wall of the thickness of cartridge paper; when suspended from one end it stretches, so as to measure 36 inches, and can easily be made to measure more; but when placed flat upon a slab, so that it lies easily and naturally, without any tension upon its walls, it measures 34 inches; and I believe this is its true length. When lying in this position, its circumference is 2½ inches at one end, and 1½ at the other, and it gradually tapers from the broad to the narrow end. Its color is light-grey, and it has a general resemblance to wash leather, and there are a number of holes in its walls, apparently the result of tearing. Its outer surface is rough, finely granular and colored brown, so that it looks as if sprinkled all over with coffee grounds; whilst its inner surface is quite smooth, and of an ash-grey line, but in no part of it are any traces of valvular construction to be seen, nor has it the general appearance of a mucous membrane. Under the microscope a membrane of connective tissue shows much granular matter, a great deal of blood, and

There are many other varieties of white grapes, a few of which are mentioned above. These are the ones which are most common in California, and some of them are grown in other parts of the world. A number of the other varieties are more common in other parts of the world, and some of them are grown in California. A number of the other varieties are more common in other parts of the world, and some of them are grown in California.

The skin itself was somewhat tough and was "teased" out with difficulty. Its structure was a felt-work of fine twisting and curving fibres, crossing each other in all directions, and entangling in their meshes granular matter, and blood pigment and corpuscles; these fibres had a homogeneous, almost transparent appearance, and presented no definite structure, nor did they resemble any of the normal fibrous structures found in the body.

"This specimen is a membranous exudation cast from the intestine; judging from its calibre and the fact that it gradually tapers from one end, I think it has probably been shed from the upper part of the large intestine."

HYSTERICAL PARALYSIS.

By Asst. Surgn. Romanath De.

Madagascar.

On the 10th April last, I was called to see a respectable Hindu girl, aged about 15 years, at Kulpaddi—a village three miles down the river—who was laid up for about a week with an attack of paralysis of the left lower extremity, which the local *kabiraj's* and a whole host of charlatans had pronounced to be the premonitory symptom of a grave disease, viz., hemiplegia.

Taking into consideration the age of the girl who is a nullipara, and subject to dysmenorrhœa, and the peculiar nature of the disease, I was led to believe that this could not but be a case of hysterical paralysis. With this impression in my mind I started in a boat with no other medicine except a small electro-magnetic battery, and on reaching the destination, enquired whether the girl was ever subject to any hysterical fit, to which none could give a satisfactory answer, except the husband, who stated that she was seen occasionally falling into a state of stupor, lasting for a very short time only.

When I saw the patient, I found her lying on her back in a bed on the floor of the room, and on examination ascertained that there was partial sensation in the limb but complete loss of motion.

I then commenced applying the battery along the course of the sciatic, popliteal and tibial nerves, the muscles supplied by them responding to the stimuli, and had not continued five minutes when she had a fit—the typical hysterical fit, noticed by the family for the first time—which lasted for about a quarter of an hour.

Edinburgh Medical Record

10th June, 1898.

PROFESSOR RUTHERFORD ON THE STUDY OF PHYSIOLOGY.

There are many ways of doing things, but the great object should be to determine the speediest and best way of doing them. To have determined this with reference to the study of a Science or an Art is to have got over half the intellectual battle so hard. It is not every teacher, however, who is able to tell a student the easiest way of mastering a subject; for to be learned and to be able to teach are widely different things. Did our space permit, we would gladly therefore have reproduced in full the introductory lecture to the physiological course in the Edinburgh University delivered by Professor RUTHERFORD on the method of studying a natural science, such as Physiology. Dr. RUTHERFORD has been a science teacher for over thirty years, and has studied in several schools in different countries; so that exceptional value is to be attached to his experience and counsel. The first part of his lecture reminds us of an oft-asked question, *viz.*, whether private study or a public school training is preferential? And Professor RUTHERFORD helps in deciding this question when he says "the primary requirement of the student is the creation of an intellectual atmosphere in which his mind can work efficiently and with comparative ease. The mere attendance at a school or university goes far to create such an atmosphere. There is a monotony and a non-impressiveness in silent and private reading which soon makes itself felt. Dr. RUTHERFORD's opinion may be summarised to be that attendance at lecture is vastly more beneficial than reading a subject privately, for the mental atmosphere created by the latter method is comparatively dull and likely to become repulsive; for, however clearly put and well arranged may be the subject read, the mind cannot be stimulated to the extent it would be by words spoken. Moreover, the lecturer who understands the subject, gives suitable emphases and modulations to each passage, imparting to it its fullest life. Companionship in schools and colleges moreover lightens labor, the interchange of ideas expands the mind, doubts are cleared and difficulties mutually explained and removed; and, above all, a healthy spirit of emulation is engendered.

It is necessary, according to Dr. RUTHERFORD, that lectures in physiology should be experimentally illustrated. These experiments are, for the most part, of a physico-chemical nature. Many of them are made on living tissues, and a small number on living animals, without the production of pain. It is best to hear a lecture on a subject and then to read the subject, it is then better grasped and assimilated. As to note-taking, a knowledge of short-hand is very helpful, and should be acquired and notes should be taken in that system. To those unacquainted with short-hand, writing a syllabus is advised. Under any circumstances it is advisable to take notes, as this practice helps much in fixing attention

to the subject. There is no such thing as a free lunch, and then, if one wishes to, he must work. A subject should be learnt by doing, and not by rote, otherwise the mental impressions are feeble and evanescent, and the subject consequently easily forgotten. The aim of education is not to pass an examination or to cram one's mind with numerous facts and imperfectly digested theories, but to train one in scientific modes of thought. Hence instruction by systematic courses of lectures is superior to the tutorial method, which tends to degenerate into "grinding." A natural science must be studied from nature—by the use of one's own senses. The mind is wearied in simply endeavouring to absorb abstract statements made in books and lectures, while it is a mental pleasure to realise phenomena by direct inspection and investigation, which moreover imprint facts vividly on the mind and tend to make one an accurate and independent observer. With regard to the power of observation, this differs in different men according to the acuteness of their mental vision. Some can concentrate their attention on an object until they have thoroughly scrutinised it, while others have no firm grasp, and have very vague impressions of what they see; but to be a skilful or a successful physician one must be intimately acquainted with nature. It is however absurd to expect anything like a close study of nature in respect to the different subjects of medical science in a five years' course of study. Professor RUTHERFORD therefore thinks that in professional examinations minute details should be avoided, as this makes candidates cram their minds for the time being with a lot of easily forgotten minutiae and gives them no time for thought and assimilation of subjects. A student should know the important facts and theories of each Science, but his knowledge of these must be sufficient and accurate and well-reasoned. There is no doubt but that the nature of our professional examinations is in a great measure responsible for the "brutening" that goes on. If the examining bodies shew from the questions set that what they expect or demand of a candidate is a good, sound knowledge of important facts, there will be an end to students storing their minds with scarcely understood details and weakly impressed facts which vanish from their minds immediately an examination is over. As Professor RUTHERFORD puts it: "no mind, young or old, should strive to become an encyclopaedia of knowledge. Life is too short for such effort, and, specially, it can never be accomplished in five short years." Professor RUTHERFORD therefore counsel moderation in examination requirements; and subjoined to severe mental discipline in mastering the chief facts of medical science and in training the mind to the habit of thought. The study of physiology is of special value in training the mind to the method and qualities of thought required by the physician; and in physiological study not only must one understand its established laws, but he must also be capable of making scientific use of the imagination, which will lead him from what is proved to what is probable, and which strives to penetrate the unknown by deductive speculation and by testing its speculation by experimental truths. Such scientific use of the imagination is the basis of invention and discovery. One must believe, however, live in the hope of establishing or some important discovery.

To make a discovery, the first essential is the formation of an idea; each idea is a likely result of thoughtful and reflective study; and the most powerful incentive to thoughtful study is critical discussion of theories. It is advisable therefore for a student to get a congenial friend to fully discuss with him the problems that arise in the course of study, and that he join a society for the discussion of medical topics.

We have but epitomised Dr. RUTHERFORD's words of wisdom in the matter of how Physiology and the natural sciences are to be studied to the best advantage, and we hope that even in the condensed form in which we have put them, our student readers will benefit by a careful consideration and digestion of them, and that teachers and examiners will help and endeavour to secure in students and candidates a sufficient, accurate, and well-reasoned knowledge of subjects instead of the evanescent encyclopaedic lore which students endeavour and are harmfully encouraged to strive to attain.

—:—:—

THE CONTROVERSY ON THE TREATMENT OF SNAKE-BITE BY STRYCHNINE.

OUR readers will recall to mind the excellent series of experiments on the antidotal effects of strychnine on cobra venom, which were published in this journal by their author, Surgeon-Captain ELLIOTT, M.B., of Madras. Our readers will also recall to mind our comments on Dr. ELLIOTT's work in this connection. We expressed our entire approval of Dr. ELLIOTT's experiments and shewed, how to our mind they very conclusively proved the truth, that strychnine was not an antidote to cobra venom. Later on we published *verbatim and in extenso* Dr. MUELLER's article in which he attempts a refutation of Dr. ELLIOTT's experiments and conclusions. We made no excuse for inserting Dr. MUELLER's article as presented to us, though at the time of its publication we expressed our opinion on it to Dr. ELLIOTT. We have waited patiently for a public expression of opinion on it by the medical press, both in the Colonies and America and in England, but we have looked in vain for the smallest notice of Dr. MUELLER's comments, while we have found, as we anticipated, that Dr. ELLIOTT's experiments have been greeted with very cordial attention by the scientific world.

The time has come however when our comments on Dr. MUELLER's article should no longer be withheld, not only in justice to our readers and to the cause of scientific investigation, but also in justice to Dr. ELLIOTT.

We would first of all point out that Dr. MUELLER's remarks have failed to elicit concern, for the simple reason that he employs the weapon of abuse, which in scientific debate can never be mistaken for argument. We regret this, as Dr. MUELLER's efforts to advance the therapeutics of snake poisoning have been praiseworthy in the extreme.

We would now draw attention to certain points in Dr. MUELLER's paper:—

(1) Dr. MUELLER accuses Dr. ELLIOTT of wilfully suppressing evidence on two heads:

(a) As to the fiasco of the TULL-WALSH incident.

(b) As to the fiasco of the TULL-WALSH incident of July 1892.

(a). We are all aware of the fiasco of the TULL-WALSH incident, which occurred in our hospital in 1892, July 20th, in which Dr. TULL-WALSH points out that he named the snakes for BAKER, who then sent them on to the British Museum.

(b). We can find no such case as MUELLER alludes to in the July or other numbers of the *Record* for 1892.

As to the other cases, which Dr. MUELLER accuses ELLIOTT of suppressing, we can only say ELLIOTT has published every available case, and it is unusual (to say the least of it) to have accused ELLIOTT of a deliberate breach of honor on such slender grounds.

Dr. MUELLER speaks of ELLIOTT's diagnostic successes in analysing records, and quotes case 39 in tables in support of this statement. The symptoms, as published by BAKER in the *Medical Reporter* of 18th June 1894, were:—

Excessive thirst, dryness of mouth and tongue, subnormal temperature, tremulousness, severe frontal headache, injected conjunctiva, dilated pupils, talkativeness and incoherence, inability to stand up and inco-ordination followed later by profound sleep and stertorous breathing.

These symptoms MUELLER ascribes to snake-poisonings. We need not point out that Indian surgeons will not agree with this opinion, and will ascribe the case as ELLIOTT did to drink.

As to the recurrent symptoms MUELLER speaks of, they are not known to us in this country, and are absolutely different from the septicemic after-effects of viper bite, which our ophiologists have so clearly described.

MUELLER speaks of the effects of strychnine on a snake-bitten man as 'mere fleabites,' 'sources of amusement,' etc.

No one who has read the case carefully recorded by Surgeon Major CADGE and Surgeon Captain PRATT in the *Indian Medical Gazette* of October 1892 could for a moment accept such inconsequent statements. These reliable observers own to having nearly lost their patients by strychnisation, and they record their sufferings graphically, though briefly.

(4) MUELLER has not ventured to answer argument by argument. He has shelved the question of the analogy between man and animals, and has thrown in some remarks bearing on a physiology which we cannot at all understand, and which we don't think any soundly-educated physiologist could hope to understand.

We sincerely trust Dr. MUELLER will take these comments in good part. They are made absolutely without any feeling of partisanship and simply in vindication of the cause of scientific research.

WILL-POWER AND DISEASE.

THERE is a great deal to be said in favor of what is best described as the "mental-science" cure for many of the minor ills of life. It is possible to throw off weakness, inactivity, and languor, and infuse new life and spirit into one's own failing system by mere effort of will. True, it is hard at first, but with every trial it comes easier, until one may almost feel that the mind has gained a supremacy over the body. It is certain that the mind can, to a great extent, control the body, and drive away much that saps vitality and undermines the strength. To keep ever before the mind the idea that will-power is one of the strongest forces in nature and steadfastly to refuse to yield to weakness, is to have gained something that one possesses, so one will ever be willing to lose.

COMMENTS AND NEWS.

ARMY MEDICAL STAFF AND INDIAN MEDICAL SERVICE ENTRANCE EXAMINATION.

THE *Lancet* says:—It is announced that in future candidates for the Army Medical Staff and Indian Medical Service will be required to make one-half of the total obtainable marks of the examination to qualify for admission into the Army Medical School, Netley, as well as one-third of the marks in the compulsory subjects of the examination. We understand that this new rule has been introduced in consequence of a falling off in the quality of the candidates competing, and that on representations which have been made to them the Secretaries of State for War and for India have been pleased to introduce it. This regulation has, doubtless, been decided upon in the hope of obtaining better professional men for the services, but we cannot help feeling that it will not have the desired effect, and that the responsible authorities would have done better had they sought to attract better men to the services by rectifying some of the terms of service which now press heavily on the medical officer, foremost among which are the, in some ways, unsatisfactory conditions under which the officers of the medical staff are serving, both at home and in India. We refer especially to the question of the unsatisfactory rates of pay which the junior ranks of both services are now drawing while serving in our Eastern Empire. We understand that the total obtainable marks at the London examinations are 4,800. Four thousand of these are awarded for the compulsory and 800 for the voluntary subjects of the examination. Referring to our past issues we find that since the appointment of the new Board of Examiners in 1898 five examinations have been held. At these examinations 60 men have qualified for admission as surgeons-on-probation for the Army Medical Staff, and 78 as surgeons-on-probation for the Indian Medical Service. Had these candidates been examined under the regulation now announced only 70 per cent. of the candidates for the Army Medical Staff would have qualified and 58 per cent. of the candidates for the Indian service. We notice that since the appointment of the new Board of Examiners the marking has been on a lower scale than it was in old days, and we feel that this new rule may have far-reaching effects unless it be modified. Either the number of candidates who are considered to have qualified at the next examination will be a very limited one, or the examiners will be obliged to be more liberal in the view they take of the candidates' answers, which will, of course, stultify the hoped-for result. The quality of the candidates competing is, of course, regulated by the advantages and the inducements which the services offer, and cannot in our estimation be altered by any rule passed by the authorities to raise the average number of marks to be gained by the candidates at the examinations."

INDIAN HOSPITAL ASSISTANTS.

THE *British Medical Journal* says:—"The 'Native Doctor' from whom the 'Hospital Assistant' of the present day is an accidental evolution, was at first little better than a compounder and dresser, who by observation, instruction and practice acquired some knowledge of diseases and its treatment, and was entrusted under close supervision with the care of the sick. Nowadays the hospital assistant has to undergo a three years' course of instruction in a medical school, to pass a tolerably severe examination, to obtain a diploma, and to prove himself qualified for medical, surgical, sanitary, and medico-legal work in positions where he is subject to very slight and distant control. Yet, notwithstanding the more scientific and complete education and training

which he receives, and the higher responsibilities to which he is entrusted, his status, pay, privileges, and prospects remain pretty much what they were when his predecessor, the native doctor, was little better than an apothecary. He receives the pay of a common clerk or, perhaps, an assistant compared with subordinates in other departments, for example, Railway, Telegraph, and Public Works Departments, his position and prospects are markedly inferior. We have received a copy of a memorial to Government drawn up by hospital assistants serving in the Bombay Presidency, in which, on considerations such as we have indicated, petition is made for more liberal pay and allowances, improved rank, title and status, increased pension, and better encouragement in the shape of promotion, honorary distinction, etc., for long and good service. The prayer of this most useful and deserving class of medical subordinates has our hearty sympathy and support, and we entertain a strong opinion that the time has come for raising the condition of life and service of a section of the public medical establishment of India which has advanced in intelligence and efficiency far above the original level, and which is likely in the future, if properly encouraged, to fulfil more numerous and important offices in the army and in civil life than at present.

THE FAILURES OF PASTEURISM.

DR. M. B. COLAH wrote a very strong brochure in defence of Pasteurism, which he read at a special meeting in Bombay last October. MR. BENJAMIN BRYAN now takes up the cudgels and reciprocates in a trenchant, terse reply, attempting to refute and put to rout DR. COLAH's facts and figures. He disputes LORD SALISBURY's dictum quoted, "that the cures for *anthrax* and *hydrophobia* are established facts." As to *anthrax*, Professor PASTEUR's treatment tested in England by KLEIN was pronounced by him to be "perfectly ineffective!" When tested in Germany by KOCH, it was found to possess very little preserving power and was a source of danger to non-inoculated men and animals. Moreover, much of DR. COLAH's information is stale and old. PASTEUR's test experiment mentioned, was performed in 1881. The more recent data are taken from FRANKLAND's work (just issued). With regard to *hydrophobia*, we are not told how many failures to inoculate from (so-called) *bona fide* rabid matter (spinal marrow) took place. That some failures did occur seems highly probable, if we may judge from analogy! Professor SHERRINGTON of London experimented on animals by inoculating them with rabid matter (spinal marrow.) The results were *absolutely negative*. No symptoms of rabies developed, although the material was *bona fide* rabid, and the inoculation carefully carried out.

DR. ZIMMERS stated last year that of all the dogs alleged to be mad only 5 per cent. were really so. A pamphlet entitled "M. PASTEUR'S Double Heatonomb" has been issued, which gives in tabular order a statement of 372 of PASTEUR's failures.

"M. PASTEUR'S DOUBLE HEATONOMB."

THIS is a tabulated statement of 372 cases of rabies inoculated by PASTEUR on various occasions between the years 1885 and 1895, all of whom recovered, in spite of the inoculation. It came out as a supplement to the *Epoch*. It begins with an extract from the report of the *Lords' Committee on Rabies in Dogs*, issued in 1887, in which DR. LAURENCE BURNTON, who was on the PASTEUR Commission which met in that year, and before whom was a similar engagement giving details of PASTEUR's nomenclature, admits the accuracy of the statements contained therein. The 372 cases are considered thus:—

- (1) Name and age of patient; (2) locality where bitten;
- (3) by what dog and when (date); (4) date of first inoculation; (5) date of death from hydrophobia; and (6)

of cholera, dysentery, and typh. Of these there were 226 cases, of which 100 died. Of these there were 100 cases of cholera, 100 of dysentery, and 100 of typh. The first case was carried out in Paris (180), Brazil (181), Italy (182), and Rio de Janeiro (183).

Dr. COLEMAN adverts to PASTEUR's claims regarding the cholera and the disease in France; but in spite of them, the physicians still devastate large tracts of vineyards, and the effluvia continue still to surface, notwithstanding PASTEUR's alleged discovery. Dr. COLEMAN also refers to SIR JOSEPH LISTER's carbolic spray, being based on PASTEUR's discovery; but SIR JOSEPH has abandoned his theory regarding this spray. Mr. BRYAN goes on to say that bacteriologists have produced but few results of any permanent value. The demonstration of the germs of cholera and diphtheria have not helped in the least to bring about an efficient cure for either disease! The microbe of rabies which PASTEUR claimed to have isolated has never yet been identified. In fact according to Mr. BRYAN's opinion the whole superstructure of bacteriology rests on a very sandy foundation.

HOW BIG AND SMALL DOCTORS ADVERTISE.

MR. LABOUCHERE in *Truth* says:—"With reference to my last remarks on doctors' advertisements, a correspondent sends me a report of a lecture delivered at Glasgow University by 'DR. BARR, the newly-appointed lecturer on diseases of the ear.' It certainly comes very *apropos*. The newly-appointed lecturer hastened to inform Glasgow that he had reason to believe 'that one person in every three has a defect of hearing in at least one ear,' so that 'there should be over 200,000 persons in Glasgow, each of whom had an aural defect.' The public, he intimated, have too little sense of the alarming condition of their ears, and the ability of the medical profession to put them to rights, but when (as the result of the institution of lectures on ear diseases at the University) Glasgow awoke to the true state of the case, 'what a boom might be expected in patients from Glasgow alone!' This is putting it pretty straight, is it not? Were this worthy professor to see a brother practitioner beating a drum outside a booth at a fair, and inviting the yokels to walk up, walk up, and be cured of all sorts of diseases, the existence of which they had never before suspected, he would no doubt form a very unfavorable opinion of such proceedings. Between the two modes, however, of stimulating a 'boom' I confess I do not see much difference."

A BREACH OF PROFESSIONAL CONFIDENCE.

A LONDON contemporary says:—"A curious trial involving points of great importance to medical men, midwives, and the public took place this week at the London Central Criminal Court. A doctor was called in to see a patient and found her seriously ill. He suspected that illegal means had been adopted to procure a miscarriage, and apparently neither the patient nor her attendant, who is described as a midwife, denied this to him. He then took the unusual step of informing the police of his suspicions, and he appears also to have assisted them in obtaining further information. The result was that the midwife, a friend of his patient, and finally, the patient herself, were arrested and tried on a criminal charge. At the trial it was pleaded that whatever the midwife did, was done with the object of ascertaining the patient's exact condition, and it was proved that the patient's husband was aware of her proceedings, and that the instruction made by the physician that there was an ulterior motive for the interview asked in the case by the third prisoner, was entirely unsupported by facts. Indeed, it would appear that at this time, at any rate, a very grave injustice may have been done. The jury found the physician 'Not Guilty.' Both the medical profession and the public will keenly question

the right of any medical man to act in this manner, and as a result of this publicity there will have been given to him in professional confidence, and which may affect most deeply the honor of his patients and the usefulness and happiness of many other people."

COMPLIMENTARY TO DR. COATES.

SAYS the *Indian Daily News*:—"The importance of having a family doctor has, in England, generally been considered as equivalent to the necessity of being provided with a family lawyer, perhaps because of the old adage: 'Tell all your secrets to your lawyer and your doctor.' Evidently, it is advisable to curtail one's lists of confidants to the minimum. In India, however, we have learned to bow to the orders of a paternal Government, and accept as our medical attendant whoever may happen to be placed in the recognized position at the time, owing to his or the patient's transfer in the interests of the public service, or consequent on a change of residence. It is new, therefore, to find one of our Aryan brothers ignoring the whole army of skilled physicians residing in the country, and telegraphing home for a doctor he already knows and appreciates. I hear that a member of the Tikari Raj, near Patna, has sent for DR. COATES, formerly Principal of the Medical College here, as well-known in the mofussil and in the native states as he was in Calcutta. We cannot but admire, not only the grateful appreciation of past services expressed by the action of this Raj, but also the ready response to such a call shown in DR. COATES' brief telegraphic reply, 'Coming.' Our old friend is on his way out, and may be expected shortly."

HEALTH OFFICERS AND FAMILY PHYSICIANS.

THE following extract from the *New York Medical Journal* will be read with interest in connection with the remarks we recently made upon the unprofessional and illegal action of the Calcutta Health Officer in his manner of dealing with small-pox patients, who were under the treatment of their family physicians. We trust that the justice of our remarks will be fully seen in the exemplary punishment which the New York Board of Health is prepared to mete to similar delinquents within its jurisdiction. The *New York Medical Journal* says:—

"It is announced that the New York City Board of Health has passed resolutions to the effect that any inspector or medical officer acting under the board who, when brought officially into contact with a case of infectious disease, interferes directly or indirectly with the attending physician's treatment, or who undertakes medical attendance in a family where acquaintance has been made in the line of his official duties, shall be dismissed from the service, unless he has been specifically instructed to perform the acts in question by the Board or by a chief of division; also that the sanitary superintendent shall instruct all the medical sanitary inspectors as to their specific duties in respect to persons sick with infectious disease."

"The statement is supposed to be a statement apparently of the sanitary superintendent's action, viz., that the passage of the resolutions was not the outcome of any special charges or complaints against any of the inspectors. This we can readily believe, for the inspectors have, we are persuaded, generally been very discreet under conditions that must sometimes have put their conscientiousness to a severe test. We have no doubt that, as a body, they are hard-working and prudent men, always ready to concede the family physician's predominance in every matter that does not involve a direct infraction of the sanitary ordinances. Still, it is exceptional instances of the contrary may have been the case. It would not be strange if it had been, for the amplified part played by the Board in the actual diagnosis and treatment of individual cases of disease in these days of bacteriology and serum

therapy and have greatly multiplied the occasions on which friction might be almost inevitable. We therefore look upon the Board's action in this matter as highly commendable."

A FEW FACTS ABOUT INTemperANCE.

THE mortality in intemperates at 21 to 30 years of age is five times that in the temperate, and from 30 to 40 it is four times as great.

| A Temperate person's chance of living is : | | | An Intemperate person's chance of living is : | | |
|--------------------------------------------|----|-------------|-----------------------------------------------|----|-------------|
| at | 20 | 44.2 years. | at | 20 | 15.6 years. |
| " | 30 | 36.6 " | " | 30 | 13.8 " |
| " | 40 | 28.8 " | " | 40 | 11.6 " |
| " | 50 | 21.25 " | " | 50 | 10.8 " |
| " | 60 | 14.28 " | " | 60 | 8.9 " |

Persons intemperate on spirits have a greater mortality (80 per 1,000) than those intemperate on beer (48 per 1,000); while those intemperate on spirits and beer have a slightly greater mortality (62 per 1,000) than those on only spirits or beer.—*Public Hygiene.*

Table showing mortality of Liquor Dealers and Men generally.

| Disease. | Men 25 to 65 years of age. | |
|--------------------------------|----------------------------|----------|
| | Liquor Trade. | All men. |
| Alcoholism ... | 55 | 20 |
| Liver disease ... | 240 | 39 |
| Gout ... | 13 | 3 |
| Diseases of nervous system ... | 200 | 119 |

| Liquor traders ... | ... | 245 |
| Brewers ... | ... | 397 |
| Inn and hotel servants ... | ... | ... |

INOCULATION FABLES.

DR. HAFKINE'S tour through the tea districts to introduce his system of inoculation against cholera afforded some amusing illustrations of the credulity of the coolie mind. On a certain garden it had been arranged that the entire labor force should be inoculated the next morning. When the time arrived, however, not a single coolie was to be found in the lines, excepting an old woman who could not walk. It was then discovered that a report had circulated amongst the coolies that the doctor cut the patient open on either side of the stomach, and then passing a large towel right through, wiped out the whole of the intestines. It was not until the Manager "Sahib" had been inoculated before them that any of the coolies would consent to be performed upon.

A WORD IN FAVOR OF HAFKINE.

A tea planter in Assam, writing to the *Indo-European Correspondent*, says:—"The professor inoculated 1,154 coolies here once, and 785 of these coolies a second time. (Two inoculations are best, he says). We have had 33 cases of cholera here, 13 of them fatal, but in only one case has an inoculated person died, and that person was only once inoculated. There was a case this morning and the person attacked by cholera was the only person in a household of five who has taken cholera.

"This immunity, or almost so, from fatal results seems to have made a great impression on the coolies, and although at first they were rather reluctant to try it, as it involved two days' fever and loss of work, later on they flocked in in crowds,

and many hill-tribe people. We have not a few other coolies inoculated; so that there is an opportunity of comparing which is best when attacked. The professor does not, I think, state that it gives absolute immunity. Vaccination against small-pox does not do so either, but they usually rob them of their virulence and fatal results. We are keeping careful statistics here; and will be able to judge better next year."

INTRA-UTERINE INJECTIONS BY THE ANCIENTS.

DR. KOROMILAS, a Greek physician, thinks it is evident from their writings that HIPPOCRATES, ORIBASIOS, PAULUS AEGINETA and GALEN knew of the use of intra-uterine injections. HIPPOCRATES divided the female genital organs into three parts: 1, the external organs; 2, the genital canal or vagina; 3, the uterus; and had a separate remedy to inject into each—wine and honey for the external parts, "goose grease" for the vagina, and wine and oil for the uterus. DR. KOROMILAS believes that HIPPOCRATES was the first to make intra-uterine injections.

INSOMNIA.

It is pointed out by MR. HUXLEY that nature's plan for curing insomnia is to limit the supply of oxygen to the blood, as the cat and dog bury their noses in some soft hollow in their hair or fur; birds put their heads under their wings and soon fall asleep. MR. HUXLEY suggests that those suffering from insomnia should cover their heads with the bedclothes and breathe and re-breathe only the respired air; when drowsiness is produced it is easy to go on sleeping, and the bed covering can be pushed aside and as much fresh air obtained as is needed.

SHORT ITEMS.

Surgeon-Major Clarence Smith, Madras has been offered a chance of escape from the disastrous consequences of "the phantom kiss," in as much as the Secretary of State for India has now given him the option of a trial by Court Martial. Should Dr. Smith be cleared by this tribunal, he will be re-instated into the Indian Medical Service.

Although it would not be illegal or constitute infamous conduct to advertise notice of removal, it would contravene the ethics of the profession. The most unexceptionable mode, to notify change of residence, is to transmit an autograph note to *bona-fide* patients or to enclose an ordinary address card with "Change of Address" inserted at the top, the old address, in the lower right corner, being defaced by a black line, and the new one engraved in the left-hand corner.

The driest place on earth is in Egypt, along the Nile, and especially between the two lower falls. The inhabitants have never seen rain, as it has never been known to fall there.

When told that water falls from the skies in other parts, they first smile and then look sorry to think that white men will tell such deliberate falsehoods and expect the Egyptians to believe them.

The *New York Medical Journal*, in commenting upon the way in which private practitioners are handicapped in India by officials, says:—"We assure our Indian brethren of our sincere sympathy and of our hope that their just aspirations may meet with full fruition. Let them not be discouraged."

Dress materials vary greatly in their capacity for retaining odors; silk allows almost all odors to pass through without leaving any smell behind; linen holds them fast; wool, though it lets many smells pass through, retains the odors of decay, like that of a corpse.

Surgical interference is not advised, except when grave symptoms intervene,

OUR LONDON LETTER.

(From our own Correspondent.)

THE weather here is variable, but is settling down with the promise of a brilliant spring.

Among the empty and fertile discussions raised in medical circles is the following:—Should every medical practitioner be termed Dr. or should this title be reserved for holders of the M. D. degree alone? "Certainly important interests may or may not hang upon the upshot of this time-worn and much-debated question, but up to date we find too much space and time have been devoted to it." We feel all but convinced that it should rest upon the unanimous decision of the university authorities throughout Great Britain, whose business it should be to look after the status of their alumni.

Among surgical items, the journals during February and March have teemed with case reports and letters advising castration as a means of radical cure for hypertrophied prostate; the results obtained by this operative measure would seem to be encouraging.

DR. B. T. HEWLETT has given us a short but interesting account of how tetanus antitoxin may be prepared, and quoting ROUX, VAILLARD and others on the subject of immunisation.

DR. HADDEN has just been sued on the plea that he had wrongly diagnosed a patient's complaint as small-pox, and thus notifying the same to the authorities, the jury awarded £100 damages.

Several cases of polydermia laryngis were shown at a meeting of the Laryngological Society. In one case that of a woman, it came on 20 years after a confinement. Alcohol and beer were mentioned as likely causal factors of the disease. This case was treated by painting with perchloride of iron for three weeks. She regained the use of her voice.

At the Harveian Society Dr. TAYLOR read a paper on syphilitic diseases of the brain, classifying them as follows: (a) meningitis; (b) gummatous of meninges, with secondary affection of the brain; (c) diseases of blood-vessels, arteritis and periarteritis. DR. GUTLINE is responding, mentioning temporary spasm and ophthalmoplegia as minor symptoms of such lesions.

A note of importance to Indian practitioners comes to us from a pamphlet of PANTALONI, wherein he reports four cases of liver abscess successfully treated by operation. And what is most pertinent is the fact that the patients were residing at Marseilles, and curiously enough had never been out of France, and he adds a crucial remark, viz., that three of these cases had a definite and clear history of dysentery.

MR. HULKE, late President, R. C. S., was interred at Deal. The following medical bodies were fully represented at the ceremony, of the Royal Colleges, Royal College of Surgeons, the laboratories, R. C. P. and R. C. S., the Middlesex Hospital and Medical School and the Clinical and Geological Societies.

The result of the Royal Opium Commission to India is that legislation shall remain practically *in statu quo*. SIR WM. ROBERTS adds to the report a note on the medical aspects of the question, and MR. HARIDAN VEJARIDAS records that the increasing consumption of alcohol in India is a subject of far greater importance than that of opium.

Asent the Medical Register for 1895, there has been a decrease in Ireland since last year, both in students and practitioners enrolled, whereas in Scotland and England the numbers have increased.

DR. W. B. THORNE gives us some account of how cardiac affections may be treated by baths and exercises, but we believe the credit of this form of therapeutics is due to Germany in the person of DR. SCHOTT.

We have seen too, a number of cases in which influenza has been complicated by acute rhinitis, post-nasal catarrh, pharyngitis and tracheitis.

Diphtheria, which had been declining here, has again increased in the number of persons attacked during the week, as estimated by the increase of admitted cases to the various metropolitan hospitals. The etiology and pathology of this disease still continue to be warmly debated at some of the leading medical societies' meetings.

A disease well known to practitioners in the Far East called "Otomycosis," supposed to be caused by bathing in filthy wayside pools, is excessively common among Malays and Chinese coolies; the latest treatment being to wash out the meatus with a solution of one part of hydrargiri perchloridi in 1,000 parts of rectified spirit, followed up by the application of dry boric acid.

We regret to have to record the death of SIR W. SCORRELL SAVORY, Bart., F.R.C., Surgeon Extraordinary to the Queen, Consulting Surgeon to St. Bart's, and Surgeon to Christ's Hospital. The cause of death was influenza with intense pulmonary congestion and cardiac failure. He was a commanding figure, both as a surgeon and a gentleman; he was a fluent and facile orator, was born in 1826, nominated Assistant Surgeon in 1861, and full Surgeon in 1867, retaining his post till November 1891, when he was placed on the consulting staff. He had been H. S. to the renowned Sir W. LAWRENCE, and was elected a Fellow of the R. C. S. He became President of the R. C. S. England in 1865. He will be much missed in medical circles. Another eminent professional author, namely, DR. HACK TUCK, M.D., LL.D., F.R.C.P., passed away on

March 5th last. In 1856 he was associated with DR. BUCKNILL as co-author of *Handbook of Psychological Medicine*. He was 18 years ago co-editor of the *Journal of Mental Science* with DR. CARR, DR. FRYER was President of the Medical-Psychological Association of Great Britain. It was not until 1882 that his great work, "a voluminous Dictionary of Psychological Medicine" was published. He died in Welbeck Street, where he took up his abode as a consultant in 1857.

Surgeon-General THOMAS RYAN, M.D., died at San Remo at the end of February of this year. He became Assistant Surgeon in 1857. He served with the 8th Hussars during the Indian Mutiny (1857-1858), was present at the capture of Kotah, and the actions of Kotana and Koonbana (medal with clasp), and in the Afghan War 1878-80 (medal).

DR. GRUBE (of Neuenehr) reports four cases of psoriasis associated with diabetes, and does not believe this to be a mere coincidence.

Cases of melancholia have actually been cured by the induction of thyroïdism by the use of thyroid gland extract.

A fund is being raised to erect a suitable memorial to the late Oxford Regius Professor of Medicine, Sir HENRY ACLAND and among the subscribers are the Prince and Princess of Wales, Princess Christian, Duchess of Albany, LORD ROSEBERRY, MESSRS. GLADSTONE and RUSKIN.

Among late occurrences there has been an outbreak of rubola on the training ship *Britannia*.

The difficult question has been propounded—Is a doctor, when called in to attend a woman whom he considers has had an illegal operation performed for the induction of premature labor, to act as an amateur detective? We fancy not, but in the event of death he should certainly lay all the facts observed, before the police.

DR. C. F. ARMAND SEMPLE, M.D., F.R.C.P. London, the well-known teacher and author of "Aids to Materia Medica, &c.," has passed away at the age of 50.

Reports of tetanus cured by antitoxin are getting more numerous. The treatment of snake-bite has been criticized by one of our contemporaries. *Strychnine* has not had a scientific trial, nor has any other efficient means of saving the ophidian punctured patient as yet. Soluble hypodermic of strychnine sulphate gr. $\frac{1}{10}$, repeatedly injected are the most efficacious and convenient remedy we at present possess.

DR. DUJARDIN BEAUMETZ, an eminent French therapist and Editor of the *Bulletin de Therapeutique*, is dead. He was elected a member of the Academy of Medicine in 1880.

AN ASCARIS IN A PELVIC ABSCESS.

KOON states that during the removal of a pyosalphix a small abscess was discovered in DOUGLAS'S pouch; its cavity lodged an ascaris. No communication with the rectum could be found. The patient died of purulent peritonitis on the third day. At the necropsy a perforation was discovered at a point where an adhesion had been apparent. Two fistulous tracks led from the rectum into the cavity of the abscess where the ascaris was found. KOON believes that the ascaris had burst into the rectum, the peritoneal effusion passing from the bowel into the abscess cavity. B. M. F.

Current Medical Literature.

MEDICINE.

Tight-lacing and gall-stones.

ACCORDING TO DR. MAROAND, the relation of tight-lacing to the development of gall-stones is rendered very clear by noticing the situation of the gall-ducts in the liver deformed by tight-lacing. The furrow caused by lacing runs directly across the right lobe of the liver, as the result of which there is a tendency to atrophy of the gall-bladder. When tight-lacing has been practised to an extreme degree, an artificial fissure is formed in the liver, giving rise to what is termed the "lacing-lobe," which carries with it the gall-bladder. The constricted portion of the liver is found to be just at the point of junction of the gall-bladder with its duct. In these cases, according to the author, it is common to find the gall-bladder greatly distended, extending far beyond the border of the liver, and frequently an examination made *post-mortem* reveals the presence of gall-stones. Stagnation of the bile is well known to be one of the most important causes of the formation of gall-stones. A change in the composition of the bile, from catarrh resulting from congestion of the mucous membrane and the thickening of the bile due to failure of the gall-bladder to completely evacuate itself, gives rise to formation of small masses which serve as nuclei for calculi; hence anything which obstructs the free outflow of bile through the cystic duct must favor formation of gall-stones. MAROAND is also of the opinion that many cases of cancer of the liver should be attributed to tight-lacing. It is only a few years since LANGENBECH was obliged to open an abdomen to remove a "lacing-lobe" of the liver which had been so completely separated from the rest of the organ as to cause its death, rendering its removal necessary. In view of such facts as these, it is the duty of every physician to take special pains to warn his patients against the evil effect of this pernicious practice. Few women are conscious of the fact that they are injuring themselves by tight-lacing. But physicians generally preach to deaf ears in an audience composed largely of votaries of fashion.—*N. Y. Med. Rec.*

Hemiplegia without Brain Changes.

DR. JACOBSON of Copenhagen has observed six patients in whom, clinically, the usual symptoms of a typical apoplectic attack were present, but careful examination of the brain failed to reveal any lesion except wide spread arterial sclerosis. He also collected the records of thirty-two other cases described by various writers, and by a comparison of these with his own cases he finds that the hemiplegia in those patients manifests itself during an illness of some kind, most frequently during uremia, but also during phthisis, or after pneumonia, lead-poisoning, or puerperal fever. The hemiplegia present in all respects the same as that associated with a definite local lesion and is usually fatal soon after its onset. DR. JACOBSON believes that in these cases the hemiplegia depends upon some circulatory disturbance, determined possibly by some inequality of pressure on the two sides of the brain, and that the cases usually end fatally because of the advanced age of the patients and the arterial sclerosis which is present, assisted perhaps by the toxic condition.—*Lancet*.

The Communicability of Leprosy.

BURNES has made some interesting observations on this point in the poor houses in Fiji. Though leprosy has existed for long there, it had been noticed of recent years that the number of fresh cases showed an increase, and that the epidemic leprosy exhibited a progressive character. In the poor houses after a series of cases occurred, of course most in

aged persons; of these some had lived from fifteen to twenty years in the house, but in all cases on less intimate association with leprosy subjects could be proved. Most of the cases assumed the tropho-neurotic type. The observations described serve to indicate the danger of prolonged coexisting with infected persons. As bearing on the treatment of leprosy, a case is related in full, in which guaiacum balsam applied externally and administered internally for nearly a year was shown to the Medical Society of Liverpool as cured, was discharged, was shortly after re-admitted with oedema of the face and extremities and a recurrence of the disease.—*Brit. Med. Jour.*

Alleged exceptions to Collier's Law: Is Congenital Syphilis Infectious?

IN THE *British Medical Journal*, DR. H. W. FARRER throws doubts on the truth of this "law," at least at the present time. During some ten years' work in the outpatient department of the Children's Hospital at St. Mary's, he scarcely remembers to have seen a single reliable case of infection by a congenitally syphilitic father. He accounts for this immunity thus:—"Perhaps a condition of syphilisation is being gradually brought about; whereby the intensity of the poison is being slowly attenuated; or are the earlier recognition of the disease in parents and its more thorough treatment responsible? In other words, has inherited syphilis changed in type since COLLIER laid down his law? and is this the reason why so few exceptions to this law are found? If children do not infect those who are not related to them, it is not surprising that the mothers who have borne them should escape."—*Univ. Med. Jour.*

A new and distinguishing Sign of Latent Aneurysm of the Aorta.

THIS sign, according to W. C. GLASGOW (*New York Medical Journal*) is the presence of a systolic sound in the brachial artery, synchronous with the cardiac systole, and sometimes accompanied by an arterial murmur. When this sound can be heard, and aortic regurgitation can be excluded, a positive diagnosis of aneurysm can be made, even in the absence of all other signs or symptoms. The sound is due to the rapid tension of the walls of the only partially-filled artery, due to the sudden impact of blood at the heart's systole. In pure aortic regurgitation the sign is always present; in two out of six of the reported cases of aneurysm the diagnosis was made from this sign alone four months before the appearance of the recognised physical signs. In all six cases the systolic sound in the brachial artery was present; five were intra-thoracic aneurysms and one abdominal.—*B. M. J.*

Cramps as a sign of Diabetes.

SIR BENJAMIN WARD RICHARDSON (*Apothecary*) calls attention to the occurrence of cramps in the lower limbs in cases of diabetes. They are rare by day, and most common at night. They are very painful, although not of long continuance. They occur principally in the muscles of the calf of the leg, but they may also involve other leg-muscles and, at times, even distant muscles. In conjunction with this condition there is sometimes a painless motion or twitching of the leg-muscles, observable mostly in the early morning after good sleep, and lasting two or three hours, but passing away during the day. These movements may number thirty or forty in the minute.—*Med. News*.

SURGERY.

Statistics of Intestinal Excisions.

E. BREUER publishes in *Zeitsch. f. Chirurg.* his statistics of excisions of the intestines in THANNHARDT's clinic at Bonn for the last ten years. They number thirty-three as follows: Five for strangulated hernia, eleven for artificial anus following strangulated hernia, two for stone, one for

operation, for the local stricture following perityphilitis, and for the local stricture from a ruptured colon, three fistulous openings led to tuberculous abscess for tumors. These three cases resulted in twenty-one cures. An examination of these statistics shows that an artificial anus gives better results than intestinal resection in the treatment of strangulated and gangrenous hernia. Also that in this case it is the rule first to create an artificial anus, and, if necessary, later to resect the intestine.—*N. Y. Med. Rec.*

On the prophylactic treatment of Ophthalmia Neonatorum.

CREDE in 1884 published a paper on the prophylaxis of ophthalmia in newly-born children, and the method he advocated was the instillation into the eyes of a drop of a 2 per cent. solution of nitrate of silver. His statistics proved without doubt the immense value of this plan, and there is no question that it is thoroughly efficacious; but, unfortunately, it sometimes causes a considerable amount of swelling of the eyelids. Nothing seems to answer so well as nitrate of silver, so that BUDIN has recently made experiments with weaker solutions of the same substance. Instead of using a solution of 1 in 50, as advised by CREDE, he employs a solution of 1 in 150, which has the great advantage of causing no irritation or swelling of the lids. He has watched the results of this method in 2,004 cases, and among all these there have been only two cases of purulent ophthalmia. In one of these cases, owing to an oversight, the prophylactic solution had not been used, and in the other the ophthalmia which showed itself on the second day was cured by the eighth. All the above cases occurred in hospital practice, but he states that he has had equally good results in private practice from the same method of treatment. The occurrence of purulent ophthalmia in the proportion of 1 to 1,000 cases shows that the employment of a solution of nitrate of silver of the strength described above is quite as efficient as the stronger solution recommended by CREDE, and moreover is free from the disadvantages possessed by the latter. The farther preparation of irrigating the mother's vagina at the commencement of labor with a solution of perchloride of mercury 1 in 4,000 should not be neglected.—*Practitioner.*

Successful Laparotomy for Revolver Wound of the Abdomen in a Pregnant Woman.

M. ALBARRAN presented to the Société de Chirurgie a young woman aged nineteen years who was admitted to the Hôpital Cochin for a bullet wound in the umbilical region at a spot four fingers' breadth from the median line. Five hours and a-half after the receipt of the wound she had vomited only once—during her removal to hospital. The patient was collapsed, and there was ascertained to be some dulness at the lower part of the abdomen. A penetrating wound with internal hemorrhage was diagnosed, and immediate laparotomy was had recourse to. During the preparations for the operation the state of the breasts led to a vaginal examination, and a pregnancy advanced to from the fourth to the fifth month was detected. Four wounds of the small intestine, necessitating the resection of twenty centimetres of the bowel, were seen directly the abdomen was opened; a fifth intestinal wound was sutured, and search for the source of hemorrhage which continued, revealed a perforation of the mesentery involving a branch of the superior mesenteric artery, which was tied. The fundus of the gravid uterus was the seat of a small wound through which protruded a loop of the intestinal cord. Wishing to terminate the operation promptly, M. ALBARRAN sutured the loop on a level with the vaginal surface, the stump being returned into the uterine cavity. The abdominal incision was then quickly

closed. The case was reported by the author with much interest on account of the late date of the operation.

The Triumph of Peace in a Dangerous Operation.

THE session of the LANCET on Wednesday, 18th, was made remarkable by the presentation of a patient by M. PEAN.

This patient had had a carcinoma of the larynx, and to relieve it, it was necessary for M. PEAN to make entire extirpation of the larynx, the superior portion of the Oesophagus and the inferior portion of the pharynx. Not only did the patient support the mutilation, but by means of a prosthetic apparatus constructed by M. NICOLAI, under the direction of M. PEAN, the organs were replaced, so that the patient could breathe, eat and drink. Not only that, but the apparatus allowed the patient to make articulate sounds, so that speech could be understood. It is two years since the patient was operated upon, and the crowning glory of the operation has been the phenomenal, nay, the brilliant success of the artificial larynx. In former times the saving of the life of a patient so afflicted would in itself have been a triumph of surgery, but to replace lost parts with apparatus of such delicacy and usefulness seems to represent an art almost superhuman.

A new Operation in Glaucoma: Sclerotomy.

NICOLAI recommends the following operation with a very narrow knife: The blade, with cutting edge downward, is introduced in the sclero-corneal margin in the inferior angle of the anterior chamber, passed horizontally across the anterior chamber parallel to the iris, and is brought out through the sclerotic. The blade is then turned on its axis ninety degrees with the edge toward the iris. This makes in the sclerotic an incision perpendicular to the first, and the aqueous humor at once pours out. The blade is then rapidly withdrawn, and the iris is divided at its peripheral attachment throughout the length of the wound.—*Rev. gen. Ophthalm.*

Treatment of Gonorrhoea.

DR. H. M. CHRISTIAN claims that irrigation of the urethra with potassium permanganate, 1 to 4,000, doubled in strength the second week, is the best remedy for simple non-infectious urethritis. The irrigations are made daily with about one quart of a warm—not hot—solution, the patient standing and the reservoir at a height of six feet. A cure can be effected in from ten to twelve days. This cannot be solely relied on for a specific urethritis, but to a certain point he considers irrigation the proper treatment—relieving *odor-urinae* and chordee promptly and largely preventing such complications as total urethritis and epididymitis.—*Jour. of the A. M. A.*

Mastoid Suppuration.

THE technique of operating should vary with the nature and needs of the case. Usually a fibrous incision close behind the auricle, free exposure of the bone, and penetration by the gauge close behind the auditory canal below the level of its upper margin and the *apex supra meatus*, is safest and surest to reach the antrum.—*DR. RANDALL, N. Y. Med. Rec.*

Small Tympanic Perforations

DR. HARRIS says, may be positively diagnosed by blowing finely pulverised boric acid against the drum until it is coated. Examination a few hours later will show a dark spot, where the secretions have passed through.—*N. Y. Med. Rec.*

Contracted Uterus

Is alone sufficient to cause uterine inflammation by reflex irritation, and when such a condition exists, treatment must be directed against the uterine system of the organ.—*DR. WHITE, K. Y. Med. Rec.*

Permanent Transplantation; the cause of Failure and the Remedy.

GUERARD states the following advantages for his method of transplanting:

1. It permits of the use of as large a graft as may be necessary, yet the elastic openings in the flaps, if properly made, will hold it in good position.
2. The elastic band also gives circular and uniform union without any bulging at points intervening between the flaps because of the size of the graft.
3. It furnishes the largest surface possible for union, offering the best opportunity for healing in a manner to allow the greatest freedom for the passage of nutritive elements through the lymph channels of the corneal tissue.
4. Large additional channels of nutrition are afforded, without the intervention of any corneal sows, through the large conjunctival flaps.
5. The cicatrix is placed obliquely through the most vascular area in the border of the cornea, and therefore in the most favorable position.—*Amer. Jour. of Ophthal.*

Hæmorrhage after Tonsillotomy.

MIX together tannic acid, three parts; gallic acid, one part; add a few drops of water. Knead powder until it is a hard mass; take from it sufficient to form a ball the size of a small marble. Place this on forefinger of hand corresponding to side of patient from which hæmorrhage occurs, and introduce into patient's mouth, rubbing it firmly against bleeding surface, making counter-pressure with palm of other hand on side of head over region of tonsil.—*HÖVELL.*

OBSTETRICS AND GYNÆCOLOGY.

Pregnancy with Unruptured Hymen.

GUERARD relates three new cases of pregnancy in which the hymen was persistent. In the first and second there was a protracted second stage due to the resistance of the hymen, which was perfect and very elastic. After a crucial decision the fetuses were at once delivered, but in one case the child was lost. In the third case the patient appeared to be in the seventh month of her first pregnancy, and suffered from severe pain in the genital tract. Although she had twice been operated on for atresia of the hymen, the vagina was still closed by a firm, impermeable, and tender membrane. This was excised, the pains disappeared and the pregnancy continued and ended naturally. GUERARD notes a case of bifid perineal hymen where the openings barely admitted a hair; yet the patient reached the third month of pregnancy, and abortion was induced in a manner which could not be ascertained. In considering these cases, he notes how the alkaline uterine mucus, poured out during orgasm, protects the spermatozoa from destruction by vaginal mucus.—*B. M. J.*

An unusual Obstetric Experience.

DR. E. G. BOWERS, of Fair Haven, Vt., writes:—"From a Welsh newspaper of recent date I translate the following account of an unusual occurrence, which took place during the late severe weather near Rhosmarket, Pembrokeshire, Wales: A young married woman left her home in the parish of Sertwa with the intention of walking to her mother's house in Rhosmarket—a distance of about four miles—where she intended to stay until a certain expected event should take place. Her mother walked half way to meet her, and was thunderstruck to see her carrying a newly born babe in her arms. The mother and child were taken to the nearest house as quickly as possible, where another child was born shortly after. This happened within a matter of minutes with deep snow covering the ground. The reporter does not state whether the mother or children suffered from their hard experience, but

from its silence it may be inferred that the case did not end in *Mis. Misc.*

The Etiology of Puerperal Fever.

THE *Lancet* recently printed the following deductions from DR. HENRY's remarks in a discussion of puerperal fever:

- (1). Puerperal fever is produced by micro-organisms which get into the system through wounds made in child-birth.
- (2). These organisms are transferred by contact. They are not inhaled or swallowed.
- (3). The transference of organisms is prevented by cleanliness, and the organisms are killed by antiseptics.
- (4). The hands are the usual poison-bearers; next in frequency, clothes and instruments.
- (5). Investigation of a particular outbreak of puerperal fever should begin with inquiry into the precautions taken by doctors, nurses, and midwives to secure the cleanliness and disinfection of their hands, clothes, and instruments.
- (6). There is no such thing as self-infection with puerperal fever. The causes supposed to produce "auto-genetic" puerperal fever produce, in lying-in women defended by antiseptic poison, only trivial illnesses.
- (7). The inhalation of sewer gas causes in the puerperal woman the same symptoms as in other persons. There is no good evidence that, in women protected by antiseptics from septic poisoning, it produces symptoms like those of septicæmia.
- (8). The poison of erysipelas of the skin produces in lying-in women erysipelas of the skin, and no other illness. But the poison of the disease known as phlegmonous erysipelas of cellular tissue produces puerperal fever.
- (9). The poison of scarlet fever produces in lying-in women scarlet fever, and no other illness.—*Canad. Prac.*

Cold Bath in Puerperal Septicæmia.

THE cold bath is contra-indicated when peritonitis, phlegmon of the broad ligaments, or phlegmonous dolens exists. It has proved successful when grave maladies, such as measles, erysipelas, eclampsia, or bronchitis have complicated the puerperal infection. Treatment must not be delayed when high temperature and general constitutional disturbance have set in. First of all, make sure that the uterus is free from the products of conception. Then, should the temperature rise over 101°, the bath must be used. It is often of value when the temperature is lower, the patient already suffering from headache and hot skin. The bath should be a little over 75° F., as a rule. It is right to leave the patient in till she shivers, especially when hyperpyrexia is the most marked symptom; in other respects the same precautions are needed as in typhoid fever. Subcutaneous injections of caffeine or sparteine should be given before the bath when the symptoms are severe, so as to counteract the tendency to syncope.—*Nace, in Med. Age.*

Absorptive Power of the Vagina.

COER AND LEVI have recently made some observations on the absorptive power of the vagina under various conditions of health and disease. Iodide of potassium is easily absorbed. If a tampon soaked with a 20 per cent. solution be introduced into the vagina, iodine can be found in the urine in an hour. The excretion reaches its maximum in twenty hours and ceases in forty-eight hours. Fever and pregnancy increase the absorption. Hysterectomy makes an difference. Iodine is absorbed slowly and in very small quantities, but more if fresh than if old. Salicylic acid is absorbed quickly, appearing in the urine in one hour and disappearing in twenty-four hours. Gold is very readily absorbed. Antipyrin is absorbed in an hour and a half, and is found for

and weight loss, but the respiratory action is unable to compensate with administration by the stomach. In brief, the system has exhausted its compensative power, and this is increased in pregnancy, in the puerperal state, and in pyrexia.—*B. M. J.*

Feeding Premature Infants.

CHAMBERS read notes last autumn at a meeting of the Paris Obstetrical Society, on a child which at that date was thirty-one months old, and of a fine physical and mental development. It was delivered at 5½ months, or at the latest computation at the 6th month. It weighed at birth less than 5 lbs. (850 grammes). By aid of the cowmilk and the most careful feeding it was successfully reared. MAY-CRISTEN declared that he had in one of his wards a six months' child a week old; it weighed only 770 grammes, or under 1 lb. 15 oz., but it seemed to be sinking. BUDIN observed that he had known 6½ months' babies to live for a day or two. The respiration was almost purely bronchial, the lungs did not beat, and the vesicles were found full of epithelial cells. It is easy to believe that a strong premature infant could succeed in clearing the pulmonary vesicles and live. CHAMBERS had successfully reared an infant which weighed less than 2 lbs. 5 oz. at birth.—*B. M. J.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The normal situation of the Gall Bladder in Males.

JOHN B. HAMILTON, M.D., Chicago, says:—"To find the gall bladder, draw a line from the anterior superior spinous process of the ilium to the centre of the xiphoid appendix. Intersect this with a line from the umbilicus to the tenth costo-cartilaginous junction. In the right upper triangle near the apex, but nearer the right oblique line, the fundus of gall cyst will be found. A needle thrust through the abdomen at the point indicated, will usually transfix the gall bladder. The position of the gall bladder varies with the changes in the position of the liver; in enlargements it is pushed downward, and in some cases deflected to the right."

Comparative Pathology of Necrosis.

ISRAEL summarizes his observations with vegetable cells and animal tissues into three groups of pathological changes:—(1) *Changes in the cell protoplasm* comprising: contraction of the protoplasm in clumps; disappearance of the reticulum or protoplasmic stroma; retraction of motile organs; extension of minute spherical particles from the cell substance; general granular changes in the homogeneous protoplasm; discharge of the coloring matter from blood or chlorophyll corpuscles into the surrounding fluids with alteration of the color and diffuse staining of the cells by the pigment absorbed from the fluids; alteration in the staining reaction of the cells. (2) *Alteration in the form of the nucleus* with swelling of the nucleus; dissolution of the reticulum and nucleus; formation of fine diffuse granulations and alteration in the staining reactions. (3) *Alterations in the permeability of the cells*. Further investigation is needed of definite applications.

The effect of Serum Injections on the Temperature and Pulse.

VARIOT has studied this question. All children under suspicion of diphtheria, who are admitted into the Treutmann Hospital receive, as soon as they come in, an injection of 50 c.c. of diphtheria antitoxin. This practice has given the author the opportunity of observing the children, who do not develop diphtheria, the physiological effects of the serum injections. His observations show that they cause a rise of

temperature of from 37.4° to 38.4° C. and a fall in pulse rate. At the same time the heart's action is increased, and the pulse becomes more frequent. These phenomena are explained by cardiac asthma and erythema of the skin. He thinks it probable that the artificial fever which is certain part in the process of cure, being analogous to the normal febrile reaction seen after various but possible diphtheria before the serum came into use. HARRY pointed out that in 8 cases in which he had used the serum in such patients no rise of temperature followed the injection. VARIOT thought it possible that the febrile reaction might have been overlooked in these cases owing to the temperature not being taken with sufficient frequency.—*B. M. J.*

Measurements of a Selected Venus.

OUR of five hundred applicants—most or less—for the position of a bronze Venus, in a New York show, one little woman filled the bill, whose measurements are said by her to be the following. She thus announces her statistics: "One artist says my figure is one of the best that he has ever seen, and I think myself the measurements show up very well. I am 5 feet 7 inches in height and weigh 144 pounds. My other measurements are: bust, 38 inches; waist, 24 inches; thigh, 22 inches; calf of leg, 15 inches; ankle, 9 inches; foot, 9 inches in length. My upper arm is 11½ inches, and my neck 18½ inches. Many women have figures superior to mine in certain points; but it is a most difficult thing to find a perfect, all-round figure."—*Jour. of the A. M. S.*

Post-mortem Appearances in Myxodema.

K. GRON performed an autopsy on a woman who had suffered for five years from myxodema, and found that the median portion of the thyroid gland was completely atrophied and the lateral portions reduced to mere traces. The cerebral hypophysis was hypertrophied, being the size of a walnut, and entirely filling the sella turcica.—*Univ. Med. Jour.*

—102—

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Disinfection of Tubercle-infected Houses.

Drs. DELPINE and BANSOME, of London, have made an extended study of the various methods of disinfection, and the influence of certain natural agents on the virulence of the tubercle bacillus. They sum up their results as follows:—

(1). The disinfection of rooms which have been contaminated with tuberculous products cannot be obtained by means of the fumigation methods generally used at present. Sulphurous acid, chlorine, and eucalyptus, as used under supervision by experienced municipal disinfectors, have proved practically useless. This only confirms the results obtained by KOCH and his pupils in the case of a number of other organisms.

(2). The only other method of disinfection which seems to promise more satisfactory results is the direct application of a solution of chlorinated lime to the walls to be disinfected. This method has so far given satisfactory results, but is attended with discomfort on the part of those who have to carry out the disinfection, though this difficulty may be overcome. It must be remembered that the experiments of BERTHE and FROBERG are unfavorable to the use of permanganate of potassium.

(3). Light, in the case of the tubercle bacillus, as it has been proved by several observers to be in the case of other organisms, the most important natural disinfecting agent.—*B. M. J.*

Forced feeding of Children.

NUTRITION upon a child's mind, says Dr. H. H. HARRIS, is a waste of time and money to waste the child's health. When

the fact of getting a limited amount of the clothing made
during winter months is a good thing and then make the whole
the fact of getting a limited amount of the clothing made

When appetite begins to fail, try to discover the cause and remove it. Never tempt the palate with rich, unwholesome foods, or pasting preserves, highly seasoned meats, etc. Failing appetite is often a symptom of some digestive, disease, or of constipation or clogging of the digestive or eliminative organs. Fasting for a few weeks at such a time, will give nature a chance to successfully contend with and remove the waste and other poisons which were hindering the work of nutrition.—*Good Health.*

The Stenseth Test in Murder Trials

In the Boston Medical and Surgical Journal. DR. GUSTAV LIEBMANN contributes a short paper on this subject. He states that the object of this test is to ascertain, by the presence or absence of solid contents or by the intermediary stages of digestion of food found in the stomach, how far the process of digestion has advanced, giving thus a clue as to the time at which the death of the writer has taken place, provided the time of the last meal be known. In order to arrive at an exact, or at least approximately exact conclusion, the first and imperative condition would be a uniformly established schedule of time in which the different phases of digestion should be completed. If there be such a physiological law, from which there is practically no deviation, we should place full reliance upon the test; but if there be, in healthy people even, numerous exceptions or deviations, the test must of necessity be open to errors. DR. LIEBMANN considers that this latter proposition is the true one. The different variations in the duration of the digestive process depend upon the following conditions:—1. The length of time necessary for the transformation of solids into chyme in healthy individuals varies a great deal according to the digestibility of the different foods. 2. The length of time necessary to expel the ingesta from the stomach into the duodenum in the healthy individual varies according to the quantities of food taken. Not only does it take a longer time for larger quantities to be expelled on, but the motor activity of the stomach walls is diminished by the greater distension produced by the larger amount of food present. Thus, pieces of meat are frequently found a day, or longer, after ingestion. 3. The shorter or longer stay of food depends on the amount of acidity, which varies in different stomachs even within the border lines of health. 4. Much variation even in health is caused by individuality, by presence or absence of pepsin, hydrochloric acid, psychical factors, and emotions (fright, fear, grief, or the opposite, as joy or exaltation). We see, therefore, that owing to the many physiological variations, which do not permit of any reliable deduction, even in the healthy, the forensic value of this test must be considerably limited.—*Lancet.*

THERAPEUTICS AND PHARMACOLOGY.
Gonorrhoea.

Is seen during the inflammatory stage, give *sloin pills*, 1 grain (0.065 gramme) each, to produce active purgation. This is an important point often overlooked. Not only does the *sloin* improve the appetite, but it also prevents chordee and granuloma, agnathia, and renders the inflammation less severe. Twist a fine layer of cotton-wool about a half-inch thick, cover it with ointment made of dilute nitrate of mercury to which morphine has been added 1 grain to the ounce (0.055 gramme to 31 gramme), and pass into the nostril three or four times a day. At the same time give an alkaline mixture containing *hydrocyanic*.

Eighty-five days after onset, three weeks have passed,
the infection of lower small intestine & duodenum //

giveness). In 3 groups (100 specimens of all species) with equal doses of a suspension of spores taken from the mouth. Give also to prevent the spread and growth of the disease caused by the spores. In 1 group, 100 specimens (more than 100) of all species.

One of the Best Injections for Acute and Chronic Chorea.

Salphos, 70 grains, 3 grains (0.3 gramme); *Salphos* of *ossein*, 70 grains (0.65 gramme); *Salphos* of *potash*, 5 grains (0.32 gramme); *glycerin*, 15 grains (1 gramme); *sacchar* to 1 pound (51 gramme). Always inject immediately after micturition. Introduced slowly 1 ounce (15 gramme) of the fluid into the urethra, allowing it to remain about one minute, then letting it flow out. C. L. KINGS, King's College Hospital, *Clinical Jour.*

Vaselin in Ergipelen

H. KOSTER, of the Ballingræn Hospital, has made a study of the relative value of the various common methods of treatment of erysipelas. The duration of the fever appeared to be the same when vaselin was used as when GUERIN's water, caliche applications, ichthyol and vaselin, and sublimated mercury were employed. None of these remedies were capable of checking the process with certainty, and in exceptional cases this spread over almost the whole surface of the body. The complications, especially the phlegmasia process, did not appear to be greater after the use of vaselin than when other measures were used. Consequently the author regards vaselin as quite as efficacious as the other well-known topical remedies, and preferable because inoffensive, cheap, without disagreeable odor, and producing no irritation.—*Brit. Med. Jour.*

Subcutaneous Injection of Oil for Stiffened Joints.

SIR BENJAMIN WARD RICHARDSON relates that in two instances of stiffened joints in which the inability to move the parts appeared to depend upon rigidity of the tendons and muscular sheaths, he injected, subcutaneously, olive oil into the structures and with joint motion. He found that a fluid dram of oil could be injected around the knee-joint without causing inflammation or discomfort. In one instance in which the elbow was thus treated the patient obtained, for the first time, some degree of movement after six months entire rigidity from fixation.—*Med. News.*

General Pertinaxia

KEEP the patient without food for several days. Apply two or three leeches to the most sensitive portion of the abdomen, and supplement their action by thin poultices Neapolitan ointment, or warm, soothing applications. Also give calomel in small doses after the leeches have been removed. Give internally a glass of lead water, containing 10 to 20 drops of laudanum, in teaspoonful doses, from time to time, to allay the pain. If this cannot be retained, give a small enema of tepid water containing 70 drops of laudanum. In six severe cases thus treated by the author the results were most satisfactory. —RENTILLO.

Distribution

Dr. EISENBERG, of Frankfurt-on-the-Main, reports favorable results in this disease from the administration of yucca glycosid, in the daily dose of from eighteen to thirty drops, given in three doses, suspended in milk or cod liver oil. The patients were allowed to drink beer, and were upon a miscellaneous or mixed diet. At the end of eight days there was a notable diminution of sugar. After four weeks of treatment the patients were able to partake of some saccharine foods without increased glycosuria being produced. The urinary effect upon the glycosuria was still more pronounced. At the end of several days of treatment, the amount of urine passed

...the by the The the drug was well borne.—
... ..

The Treatment of Coffer with Thyroid Gland.

During the past few years cases of goiter treated by means of the administration of thyroid gland, cases of the parenchymatous variety being selected. Of this number nine were cured or improved, while three proved refractory. Fresh uncooked glands obtained from sheep and cows were employed, and administered in doses of from 75 to 150 grains in cachets or upon buttered bread, at first every two or three days, but subsequently once a week.—*Med. News.*

Lemonade Powder.

| Tr. cinchon. comp. ed. | ... | ... | ounces iv. |

M. Sig.—Give a teaspoonful in water after each meal.—*Med. World.*

Correspondence.

VILLAGE SANITATION IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It is much to be regretted that the subject of village sanitation has not received that consideration from Government which it deserves. Although it was taken up by the Indian Medical Congress, nothing practical has yet come of it. The good effects of sanitary reforms in municipal towns have been so conspicuous that no proofs or demonstrations are necessary to prove their efficacy in decreasing the general ratio of mortality. Why should then the boon of self-government granted to us by our British Government be denied to the majority of Her Majesty's Indian subjects, namely, to the rural population? It is true that our villages are not so thickly populated as our municipal towns, and consequently the ill-effects of unsanitary conditions are not so glaring in them as in the latter places, but nevertheless the rural population suffers as much as the town population does. There is not a single village which is not visited by the most virulent types of cholera, dysentery, measles, mumps, whooping cough, influenza, small-pox, enteric fever and other epidemic diseases carrying away a number of its inhabitants yearly; while the all-pervading influence of malaria, apart from its own numerous victims, gives—to use Dr. Crookall's phrase—a new characteristic to each of

these villages. The same is true of the sanitary conditions of the villages of the Punjab and the treatment. No doubt the condition of the people and that of the in the way of effecting any sanitary improvements in our villages on an extensive scale, but some improvements can, I think, be effected in them without any or with very little increase of expenditure. An attempt to sketch out the most conspicuous sanitary defects of our villages and to hint at some of the means to remove them without any very great increase of expenditure had been made by me in a paper—perhaps then the first of its kind—in the July number of the *Indian Medical Gazette* of 1890, to which I would beg to refer your readers to see if something can be done to improve the health conditions of our villages, without much hardening the State or oppressing the people, and thus prevent a number of their fellow-brethren from finding an untimely grave.

Yours &c., PURNA CHANDRA DAS GUPTA,

Assistant Surgeon.

KISHOREGUNGE, 23rd May 1895.

POISON IN THE COMMUNION CUP.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With reference to the several articles regarding "Poison in the Communion Cup," the antidote for the poison is the old Mosaic and Levitical sanitary principle of the Passover and the giving of this mysterious Lord's Supper in one, that is, both bread and wine, mixed and combined, or as wafers dipped in the juice of the grape according to the Eastern churches. It is said to be for indicating the crucifixion of the Lord and the sacrifice of atonement that the bread and cup were given separately, and that after resurrection as the body and blood become one again, it is necessary to give both in one. Further, if there be faith, the combined one is enough, and at the same time no brother need be offended thereby on the score of cleanliness or any other sanitary principle. It is also on the law of "prevention being better than cure." It is also known that actual poison has been sometimes mixed with the cup and administered with the desire of revenge, &c. On the whole, the array of cups and glasses may be avoided if communion is held in one sacred symbol, and it will thereby prevent contagion of different kinds. Besides this rite need not be compared with the Masonic ceremony nor the "Sakid fasting." Keeping dirty Bibles too, makes men sin both ways. Purity is good. Passing the cup round in convivial parties, clubs, canteens, eating from the same dish, and smoking the same pipe are equally bad.

Yours, &c., M. VANDERBEEK,

Assistant Surgeon.

CANNANORE, 11th May 1895.

(We publish this letter, though we do not believe in its contents. There are two books of Christians having two methods of administering this sacred feast, one combines the elements, the other keeps them apart. Whether one is less or more hygienic than the other, we will not quarrel upon. There is a definite hygienic objection to a single cup, and we are sure a reform in this direction will soon come.—Ed., &c.)

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I beg a note of warning to other practitioners (through the medium of your valued paper), who might not have experienced the same danger. I had a case of dysentery for whom I thought fit to order a mixture which was prepared in a first-class chemist's establishment, and was as follows:—Pulv. gum acacia 3j, sinneraba bark 3j, parched rice 3ii, added to one pint of water, and boiled down to a decoction measuring 9oz. Strained. Dose 3j thrice daily. This was made up on the 7th February 1895, and noticing that it seemed to have rather too much of a nauseating effect on my patient, I discontinued its use after four doses. The remainder stood in the bottle, corked, which of course must have got firmly glued down; the neck-fermentation had been going on unnoticed by me, till the 21st inst., when a brother practitioner, who happened to be seated in my office, was startled by a sudden loud explosion in the next cabin (a green huize curtain separated the two) and which sounded, as he said, like a revolver shot. On stepping in to ascertain the cause, he found the bottle containing the above preparation burst into atoms with fragments of glass scattered about in all directions. This he pointed out to me.

Yours, &c., A. BEALE, J. M. S.

Asst. Surgn. in medical charge R. I. M. S. Clinic.
BOMBAY, 2nd March 1895.

A WORD TO YOUNG PRACTITIONERS—A BULL SOMEWHERE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have but just seen the issue of the *Record* containing my letter, and find that I have been credited with statements I am certain were never made. I am therefore surprised how my letter has been made to read as printed. I have been made to state "that disease exists for the pleasure of finding it out;" whereas what I stated and meant to infer was "that the satisfaction excited by the clever differentiation of disease, in the place of indifference as to the necessity of careful diagnosis, would engender the feeling that disease exists but for the pleasure of finding it out," and again I am made to state "that the best physician with the best ability is he who prescribes the greatest number of remedies" instead of "he is the physician with the greatest ability who prescribes the least number of remedies." I am sure that the statement in the preceding paragraph of my letter should have made your "men of scissors" reflect, before giving any letter such a contradictory conclusion. He might have "gone the whole hog" while he was about it, and made me state "that the best physician with the best ability is he who kills the greatest number of patients."

Yours &c., D. O. C.

21st May 1895.

We gladly allow space for our correspondents' corrections of his final letter, and we are sorry to show him his original manuscript to prove that the "bulls" originated from his cerebral garden.—ED. I. M. R.

POTASSIUM PERMANGANATE AS A FILTER.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Reading Dr. HANKE's letter in the *Illustration* of water, published in the *Standard*, I observe that his remarks about filters being a breeding source for microbes, and that he is now experimenting with potassium permanganate as a means of cleansing and disinfecting wells. As regards filters, I have always advised my friends and patients for the past twelve years to pour a kettle of boiling water through their filters and immediately after, a quart of potassium permanganate solution one grain to the ounce, and to repeat the process every fortnight. For the past six months in Cochin I have had put into the garden wells every month alternately, lime and permanganate of potash, with the result that cholera has not only been considerably reduced, but on two gardens, which were notorious for outbreaks of this disease, not a single case has occurred to date from time of using. The wells were first thoroughly emptied out by one and cleaned and also drained, besides being kept otherwise protected from external contamination.

Yours &c., ALF. MCCABE-DALLAS, L.M. Dub., L.R.C.P. &c.
KUMBHAR, 22nd May 1895.

REVIEWS.

HEALTH AND CONDITION IN THE ACTIVE AND THE SEPTENTARY. By NATHANIEL EDWARD YORKE-DAVIES, L.R.C.P., M.R.C.S., L.M., Author of "Foods for the fat"; "The Dietetics of Obesity"; "Aids to long life"; "Medical Maxims," &c. (Published by Messrs. SAMPSON LOW, MARSTON AND Company, Ltd., Fetter Lane, Fleet Street, London, E. C.) 1894. Pages 260.

This is an excellent health manual. Indeed the name of DR. YORKE-DAVIES, is in itself quite a sufficient guarantee that the work under review is sure to be a treat to the reader and a valuable contribution to contemporary literature on health and the treatment of disease by the regulation of diet. This method of cure, of the very many ailments brought on through errors in eating and drinking, though not new, is of vital importance to the patient's well-being, not only because more rational and more successful than drugging, but also because it is so often apt to be overlooked, or given a very subordinate place in treating these ailments of "high life," not only by the patient himself, but sad to say, also by his medical attendant. Hence the subject needs emphasising and recapitulation, "line upon line, and precept upon precept," and DR. YORKE-DAVIES needs no apology for placing his most useful work on the market. Nay, on the contrary, he has earned the thanks of the profession for so doing.

The work is divided up into 28 chapters, the first 12 of which are taken up with the considerations of long life, death, food and exercise, nutrition, &c., then follow 3 chapters on work, (wear and tear) exercise and rest, and wines and other beverages. The remaining 10 chapters contain the pathology, description and treatment, &c., of the following ailments:—Obesity, gout, indigestion, excessive leanness, constipation, biliousness, Bright's disease, diabetes, anemia, neurasthenia, headache, acidity and ailments due to mal-assimilation of food and errors in the mode of life.

The paper, printing and binding are excellent.

THE PULSE; or, an exposition of the pulse. By the renowned Physician, sage, SANKARA SEN, and the celebrated sage, KANADA. Translated into English from the original Sanskrit by KAPILAJI D. S. SEN GUPTA, 1893. Price one rupee.

This is a little brochure of 166 pages, and will no doubt be welcomed by many Bengali gentlemen, medical and lay, as it is written in a most fascinating, interesting manner, holding the reader's attention from start to finish. As a specimen of curious Sanskrit lore if nothing else, it is well worth possessing. Each translation is preceded by the Sanskrit quotation (in Bengali characters), which it purports to explain and amplify. Dr. S. GUPTA has performed his task with energy, zeal and an accuracy of English diction and idiom which stamp him out as a scholar of no mean attainments.

He says in his *avant-propos* "the perfection to which the ancient Hindus had carried this important branch of the healing art, (*viz.*, a knowledge of the pulse as indicating health and disease), is marvellous. The Hindu physician, by noting the condition of a patient's pulse, can predict the day—say, the very hour when he shall expire—whether he will be cured or not, and other things of a like nature (!) The accuracy with which predictions of death are made seems to confirm one in the opinion that this item of knowledge could not be attained by any other means than *clairvoyance*; unsound as it may appear to the positive intellect of Europe."

A quotation or two, illustrative of the quaint nature of the book will not be amiss.

"If a person's pulse courses like a black-bee, he will die in a day." (!) "He, whose pulse leaves its locality by half a grain of barley, will expire within three days." (!)

"When a person imbibes a sweet flavour, his pulse, courses like a peacock. (!) When he takes anything acid, being slightly heated, it courses like a frog" (!)

Air, Bile and Phlegm are the three great Humours of the body, hence "if the pulse of a person heated with the burning of fever and having his three Humours vitiated, appears ice-cold, then he will expire after three days." (!) And so on.

Such is the ancient medical lore as propounded by the great sage-physicians, SANKARA SEN and KANADA. Let him who runneth, read and reflect.

THE CITY OF GLASGOW LIFE ASSURANCE COMPANY. *Report by the Directors.*

We have before us the fifty-sixth annual report of this most excellent life assurance company, which has branches in Edinburgh, London, Manchester, Calcutta and Bombay, the head office being in Glasgow. The Bengal branch is located at 5, Lyons Range, in Calcutta, the Secretary being Mr. COLIN C. GULLILAND, and the Agents, Messrs. BARRY & Co.

The above Company is in a most sound and flourishing condition, and is making steady progress year by year. During the past year the large addition of 283,205 was made to the Invested Funds, (amounting to \$1,098,181) and a dividend of 9 shillings per share, (free of income tax)

was declared. The whole of the Funds belonging to the Company are absolutely secure. The working capital of management, &c., being very low.

Claims are paid immediately on proof of death or survivorship, and title.

Bonuses are added to policies every fifth year, and after more than 5 years' full premiums have been paid. Intermediate bonuses are given about fourth year between the periods of Division. The Company transacts all classes of Assurance business, and rates, or any other information desired, may be had on application, at any of the Company's offices.

We would heartily commend this most secure and reliable Company to our readers.

THE DROITWICH BRINE BATHS, as therapeutic agents in various diseases. By W. H. TOMLINS, L.R.C.P. (Lond.), M.B.S., (Eng.) (London: H. K. LEWIS, 136, Gower St., W. C.) 1895. Pages 22. Price one rupee.

BALNEO-THERAPY is a method of treatment though fairly largely employed, not favored with much belief as to its efficacy in the cure of disease, simply, we venture to suggest, because not carried out in a thorough, systematic, and scientific manner. But the day of a more scientific treatment of the subject of baths and water-cures has already dawned.

DROITWICH as a health-resort undoubtedly holds its own, and of late years, such vast improvements have taken place in the sanitation of the town, that settlers have flocked into it in large numbers, and a new town practically, has arisen from the ashes of the old one.

The little pamphlet treats of:—(1) The action of baths on the temperature of the body and the heat store; (2) Operation of baths on change of tissue and excretion; (3) Influence of baths on the circulation; (4) on the nervous system; (5) Electrical operations of baths; (6) Mechanical action of baths; (7) The absorption in a bath. Next in order, saline waters are taken up, and lastly, cold springs and hot springs.

Thus the subject of baths as therapeutic agents, is well threshed out in the 22 pages Dr. TOMLINS has devoted to them.

Some of the diseases in which these baths are efficacious are:—muscular rheumatism (lumbago), gout, rheumatoid arthritis, struma, malaria, paralysis, and stiffness of joints after dislocations or sprains, &c.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

The services of Surgn.-Capt. H. W. Elphick, M.B., I. M. S. (Beng.), which were placed temporarily at disposal of Govt. of N.W. P. and Oudh, are placed permanently at disposal of that Govt. from 1st April.

The services of Surgn.-Maj. R. E. H. Whitwell, M.B., C.M., I. M. S. (Beng.), are placed at disposal of Govt. of Beng.

The services of Surgn.-Capt. H. E. Frazer-Brackman, F.R.C.S., I. M. S. (Beng.), are replaced at disposal of Govt. of N.W. P. and Oudh.

The appts. of Surgn.-Cols. J. H. Newson, M.D., and J. C. G. Oatlethill, M.D., in administrative grade of I. M. S., Beng. Branch, will reckon from 1st March and 1st May respectively.

Benares Medical College, admitted into service as Asst. Surg. on 8th April.

NOTICES TO CORRESPONDENTS.

HINTS TO CONTRIBUTORS.

1. Write plainly and briefly and to the point. 2. Write on one side of the paper only. 3. Save postage by sending your papers by "Book Post," the wrapper having its sides open. 4. Every member of the Profession in India should do his little share in adding to the general stock of knowledge of tropical disease. 5. Write up interesting cases or a series of cases, give statistics bearing on the history, causation, prevention and treatment of disease. 6. Bear in mind that this Journal is a channel of communication between the members of our profession in the East; therefore send "Personal and General News items," and they will be recorded. 7. Write your views on socio-political topics, connected with the profession, official and non-official, in order to advance the interests of all sections of our country. 8. Newspapers and journals sent for notices should have the parts intended for observation marked.

C. A. T.—We understand that twenty years ago, when living was four times cheaper than it is to-day, an order was passed by the Madras Government that Hospital Assistants could charge a fee of 8 annas by day and one rupee by night for each visit paid to a patient in private practice. Recently, when reference to the Surgeon-General was made regarding Hospital Assistants' fees, this same order was quoted. We think the fee ought rightly now to be raised to Rs. 2 and Rs. 4.

J. W. (Visnagaram).—We have kept out all correspondence relating to Hospital Assistants with a good

C. W. (Calcutta).—It is well known that the European and Eurasian practitioners of Calcutta had a traitor in their camp at the Indian Medical Congress Committee. He was not of their community, but poses as one of their body.

THE MENOPAUSE

In this condition, which comes on as slowly as does puberty, and usually lasts for fairly months Dr. BYRON ROBINSON notes that the various phenomena may possibly be explained by a disturbed harmony of visceral rhythm dependant on blood, calorific and perspiratory changes acting through the nervous and circulatory systems; but the etiology and pathology of the menopause lie chiefly in the sympathetic or ganglionic nervous system; for while the systematic pathologic stages are a slow progressive process of atrophy, genital irritation or disease, indigestion, malnutrition and anaemia, the greatest points of disturbance are in the heat, sweat and vasomotor centres, according as their blood supply is deficient, disproportionate or excessive, and women, "at this period of their lives, do not suffer a thousandth as much from malignant diseases, as they do from hysteria, neuralgia, mental deviations and other affections, all pointing to an unbalanced, unstable nervous system, debility of the sympathetic axes, irritability of the cerebro-spinal and ganglionic system or reflex neuroses, in all of which a large blood supply means a vast nerve supply. Premature puberty means well-developed genitals and ganglionic nerves with a more or less highly developed abdominal brain and hypogastric plexus. And while an early or a stormy puberty respectively means a late or a stormy menopause, the disturbance at the beginning of puberty is a profound, actively, reflexly propagated process, which quickly fits the growing and changing nervous system but the menopause is a destructive process which, breaking up the harmony of the previous processes, unleashes nervous energy and circulation, and by stopping the means and causing atrophy of the genitals and hypogastric plexus administers to every viscous a greater shock than it received at puberty. Reflex neuroses point to irritation of a peripheral motor or sensory area, and objective sexual desire at the menopause is indicative of disease. The menopause is characterized by various discharges, such as leucorrhoea, metrorrhagia, epistaxis, pruritus, hemorrhages from the breasts, and the neglect of which may compromise malignant disease, and a malnutrition of the sexual organs which has a tendency to increase and which coincides with the general atrophy of the organism, the loss of weight, thinness, black teeth and perhaps diarrhoea, and the degeneration of the cellular structures are manifested with increased force at which the patient is conscious of the fact, and sometimes even of the nature of the change."

Vol. IX.

JULY TO DECEMBER.

1895.

purpose. His attitude to the officials of their grievances and disabilities is before the Government, and it would be impossible at this stage to thrust forward complaints that might harass those in authority whom we believe are strongly disposed to do justice to this useful class of practitioners.

M. A.—The Collector should pay your account in full. Don't proceed against him in a court of law.

B. M. J. (Jelhera).—Beni Madhab Tiwari, Medical Officer of Jelhera, Bihar, says:—"To all the readers of the Record I have the honor to announce that I have discovered a specific remedy for true Leprosy. I am willing to send a quantity of the medicine, with full directions for its use, to any medical brother who wishes to try it." We would be glad to receive reports of any cases of genuine leprosy treated successfully by our correspondent. Doubtless his offer will result in further trials.

T. O'C. (Buxar).—A lad who has passed the Entrance Examination of an Indian University could not do better than join the Warrant Medical Service, and while in College, attend the full University curriculum.

C. W. (Calcutta).—It is well known that the European and Eurasian practitioners of Calcutta had a traitor in their camp at the Indian Medical Congress Committees. He was not of their community, but poses as one of their body.

PAMPHLETS.—The City of Glasgow Life Assurance Company. Report by the Directors.

The Dreitelsch Brine Baths as therapeutic agents in various diseases. By W. H. Tomlins, L.R.C.P. (Lond.), M.R.C.S. (Eng.). (Publisher: H. K. Lewis, Ltd., Gower Street, London, W.C., 1896). Price one rupee.

Literary Contributions and Letters from: Surgn.-Capt. Patrick Hehir, M.D., F.R.S.E., F.R.C.S.E., D.P.H., Hyderabad; Md. Abdurrahman Khan Bahadur, L.M.S., Lucknow; E. H. Hankin, M.A., Lucknow; J. Ashburton Thompson, M.D., D.P.H., New South Wales; Alf. McCabe Dallas, L.M. Dub., L.R.C.P. &c., Kumbhir; Asst. Surgn. A. V. M. King, Bombay; Asst. Surgn. Romanath De, Madaripur; Civil Hosp. Asst. Aratshunker; Asst. Surgn. Purna Chandra Das Gupta, Kishoregunge; Asst. Surgn. M. Verghese, Cannanore; Asst. Surgn. A. Beale, I. M. S., Bombay; and others.

THE MENOPAUSE.

IN this condition, which comes on as slowly as does puberty, and usually lasts for thirty months Dr. BYRON ROBINSON notes that the various phenomena may possibly be explained by a disturbed harmony of visceral rhythm dependant on blood, caloric and perspiratory changes acting through the nervous and circulatory systems; but the etiology and pathology of the menopause lie chiefly in the sympathetic or ganglionic nervous system; for while the systematic pathologic stages are a slow progressive process of anemia, genital irritation or disease, indigestion, malnutrition and neurosis, the greatest points of disturbance are in the heat, sweat and vasomotor centres, according as their blood supply is deficient, disproportionate or excessive, and women, at this period of their lives, do not suffer a thousandth as much from malignant diseases, as they do from hysteria, neuralgias, mental deviations and other affections, all pointing to an unbalanced, unstable nervous system, debility of the sympathetic axes, irritability of the cerebro-spinal and ganglionic systems or reflex neuroses, in all of which a large blood supply means a vast nerve supply. Precocious puberty means well-developed genitals and ganglionic nervous with a more or less largely developed abdominal brain and hypogastric plexus, and while an early or a stormy puberty respectively means a late or a stormy menopause, the disturbance at the beginning of puberty is a profound, actively, depletive physiologic process, which quickly fits the growing and adaptive nervous system; but the menopause is a destructive process which, breaking up the harmony of the previous processes, unbalances nervous energy and circulation, and by stopping the menses and causing atrophy of the genitals and hypogastric plexus administers to every vicious a greater shock than it received at puberty. Reflex neuroses point to irritation of a peripheral motor or sensory area, and excessive sexual desire at the menopause is indicative of disease. The menopause is characterized by various discharges, such as leucorrhoea, bromhidrosis, epistaxis, pemphigosis, hemorrhages from the bowels, &c., the neglect of which may occasion malignant disease, due to malnutrition of the sexual organs while in a state of stagnation and while endometritis with its possible flooding is chief among the actual diseases in the menopause extensive surfaces, local death and prevalent secretions arising from low general cell formations are associated with systemic affections, in which the chief feature characterizing is malnutrition from atrophy which, by suddenly curbing blood supply from the 'an olden' degeneration of the genital system, consequently implies control of disease by a depletive treatment.

INDEX

TO THE

INDIAN MEDICAL RECORD,

VOL. IX.

JULY TO DECEMBER 1895.

▲. M. S. Officers, hard worked, 396.
 ▲ fast boy, 262.
 ▲ severe case, 357.
 ▲ successful Eurasian medical administrator, 183.
 A goat-flesh famine, 183.
 Abuse of medical charity, 17.
 Abuse of quinine. By James Harris, L. M. S., 411.
 Abdomen. Laparotomy and penetrating wounds of, 62.
 Abdominal section followed by thirst, 230.
 Abdominal disease. The physical signs of, 364.
 Abortion. Indications for induction of, 63.
 Abortion cases. What is our duty in, 101.
 Abortion. Tubal, 142.
 Abortion. Indication for induction of, 302.
 Abortion followed by perforation of the uterus, with prolapse of the intestine, 302.
 Abortive treatment of erysipelas, 431.
 Abscess. Hepatic. Incision: Recovery. By H. D. Pant, 126.
 Abscess in the iliac region, 334.
 Absorption and effusion, 268.
 Abnormal spleen. By Asst. Surgn. T. H. Aquino, L.M.S., 316.
 Acromegaly, 22.
 Action. Dual brain, 25.
 Action of iodine on the temperature of phthisical patients, 66.
 Actions and uses of disinfectants, 85.
 Action for damages for ruptured perineum, 145.
 Action for services. Physicians cannot make disclosures in, 145.
 Actions and uses of disinfectants, 210.
 Action of light on bacteria, 303.
 Action of antipyretics on the blood, 304.
 Action for medical libel, 369.
 Accessory spleen, 25.
 Accident caused by curetting the uterus, 188.
 Aconite root. External use of, 29.
 Aconite used in diseases of children, 363.
 Acute infective diseases and abortion, 231.
 Acute rheumatism, 185.
 Acute gonorrheal rheumatism, 365.
 Acetanilid heals chancroids in from one to seven days, 334.
 Administration of Gondal State for 1894-95, 292.
 Advice to young practitioners, 256.
 Advertising unprofessionally in high places, 329.
 Advantages of total abstinence. By Surgn.-Major G. F. Poyader, A. M. S., 346.
 Advancement of Hospital Assistants, 435.
 After-treatment of laparotomy, 25.
 After-histories of removal of diseased appendages, 106.
 After twenty-six years' deafness, recovery of hearing, 399.
 Aged. Care of the, 368.
 Akromegalic type of syringomyelia, 430.
 Alcoholic stimulants. Some considerations on the use of, 14.
 Alcoholism. Pilocarpine in, 27.
 Alcoholic neuritis in old age, 429.
 Alimentation in febrile disorders, 22.
 Alive at duty, 184.

Albuminuria. Bright's disease without, 60.
 Alkalinity and infection of the blood, 302.
 Alum process of sterilizing water, 303.
 All ulcers of the leg can be cured, 364.
 American opinion of the Opium Commission, 101.
 American opinions on medical witnesses in law courts, 328.
 American parable of the blacksmith and the physician, 396.
 American views of antiseptics in midwifery, 431.
 Amputation of arm for compound fracture: Recovery. By Aratshanker, C. M. S., 323.
 Amputation of omentum in hernia, 334.
 Anaesthesia from hydrate of chloral. By Surgn.-Capt. Patrick Hehir, M. D., 9.
 An automatic gallows, 27.
 An old Anglo-Indian Surgeon, 134.
 An unjustifiable job, 263.
 An act restricting the sale of poisons in India, 328.
 An anomalous monopoly, 183.
 Anti-venene: Immunity to snake-bite, 55.
 Antivenene and snake-poisons, 109.
 Antistreptococcal serum in puerperal septicæmia, 108.
 Antiseptic powder substitute for iodoform, 146.
 Antiseptic treatment of the navel in the newly-born, 335.
 Antitoxin typhoid, 233.
 Antifebrine uncertain in its effects. By Asst. Surgn. A. Beale, I. M. S., 417.
 Anti-rivisection and vivisection, 427.
 Anti-alcoholism, 428.
 Antipyrin in pruritus, 434.
 Analysis of 6,777 cases of midwifery, 63.
 Anatomy of the congenital crescent downward and inward, 144.
 Ano. Fistula in, 300.
 Anchoring the kidney, 228.
 Angina, 304.
 Anomaly. Rare obstetric, 366.
 Anthropology criminal, 189.
 Anglo-Swiss Condensed Milk, 437.
 Apomorphia as an antispasmodic. By Edward E. Balm, 7.
 Apothecaries of the civil class, 372.
 Apoplexy, 408.
 Appendages. Pregnancy and operations on the, 105.
 Appendicitis, 338.
 Appendicitis and rheumatism, 430.
 Aphorisms relating to obstetrics, 266.
 Apple dessert, 305.
 Appropriate treatment of sprains, 398.
 Aquous part of the breath. Toxicity of the, 335.
 Articles of food. Wrapping paper used for, 303.
 Artificial testes after castration. Implantation of an, 24.
 Artificial production of amyloid disease, 231.
 Artificial abortion induced by curettage, 432.
 Artificial dilatation of the cervix in puerperal eclampsia, 432.
 Are chemical examiners infallible, 257.
 Are sanatoria for consumptives a danger to the neighbourhood, 433.
 Army Surgeon. A female, 263.
 Army Nursing Service in India, and the British soldier's opinion of it, 290.

Army milk supply, 373.
 Army Medical Department and Lord Wolseley, 426.
 Army Medical Department, 357.
 Arterio-venous anastomoses, 433.
 Arsenic occasionally present in normal urine, 222.
 Ascaris lumbricoides. Membranous enteritis associated with, 61.
 Association of medicine with religion, 222.
 As others see us in our views of opium, 328.
 Assam. Kala-azar in, 262.
 Ascidic green fluid, 468.
 Asst. Surgn. John Rowley, I. M. S., 349.
 Atrophy. Pathological anatomy of progressive muscular, 367.

B.
 Bacillus anthracis. A new variety, 26.
 Bacilli. New method of detecting them in sputum, 308.
 Bacteriology in practical medicine, 56.
 Bacteria. The action of light upon, 303.
 Bacteria in variable forms, 433.
 Bactericidal properties in the vaginal secretion of pregnancy, 432.
 Bacteriologic diagnosis for diphtheria, 433, 241, 261.
 Baby. A manual for mothers and nurses. The care of the, By J. P. Crozer Griffith, M. D., 69.
 Baby Tongue-tied? Is the, 105.
 Barbers and hair-dressers, 108.
 Banknotes. The death of, 303.
 Bengal charitable dispensaries, 135.
 Bengal Government and medical certificates, 141.
 Benefit to ear patients from nasal treatment, 41.
 Belladonna in myovitis. By Asst. Surgn. A. Beale, I. M. S., 176.
 Belladonna in catarrh caused by potassium iodide, 304.
 Beri-beri. Clinical features of. By Surgn.-Major B. Basu, I. M. S., 165.
 Bile. Surgn.-Lieut.-Col. J. M. Coates, M. D., 89.
 Bile-Surgn. Lieut.-Col. Wellington Gray, I. M. S., 322.
 Bilious attack. Pathology and treatment of an ordinary, 298.
 Bile and biliousness, 183.
 Biliary cirrhosis in children, 299.
 Biliary cirrhosis in children, 394.
 Bilateral brachial paralysis, 186.
 Bite. Snake, 332.
 Birth of child with rupture of membranes, 188.
 Blood in chronic cyanosis, 231.
 Blood. Nucleated red corpuscles in the, 231.
 Blood. Action of antipyretics on the, 304.
 Blood in syphilis, 367.
 Blacksmith and the physician, an American parable, 396.
 Book. Kissing the, 65.
 Bombay medical awards, 373.
 Bombay subordinate medical department, 373.
 Bombay Presidency medical work, 426.
 Boiled wheat with lemon sauce, 234.
 Boy. A fast, 262.
 Borax as an aid to the digestion of milk, 338.
 Bright's disease without albuminuria, 60.
 Brain preparation. Method of making a permanent dry, 64.
 Breasts during nursing. To dry up the, 66.
 Breast. Hysterical, 302.
 British Law of infanticide, 258.
 British soldier's opinion of the present Army Nursing Service in India, 290.
 Brevities. Obstetrical, 267.
 Brevities. Therapeutical, 269.
 Brevities. Surgical, 301.
 Brevities. Pharmaceutical, 370.
 Brevities. Medical, 398.
 Broth made of vegetables, 338.
 Bronchitis. Infective, 186.
 Broncho-pneumonia containing a pathogenic bacillus, 433.
 Breathing. To practice deep, 402.
 Buddhism. Dr. Waddell on, 20.
 Burma. Sanitation in, 37.
 Burmese Kiveria. By Asst. Surgn. Arthur Mohand, I. M. S., 160.
 Burns and scalds. Treatment of, 234.
 Buboes. Position of, 271.
 Bubo, treated by plain water dressing. By S. M. Kailie, C. M. S., 418.

C.
 Case of phlegmasia dolens of the arm. By John Morton M. D., 10.
 Case of pneumonia treated by wet sheet packing of the chest. By Asst. Surgn. P. C. Das Gupta, L. M. S., 192.
 Case of Tetany. By Jos. P. Barboza, 134.
 Cases of castor oil poisoning. By B. B. Chatterjee, 120.
 Case of yellow oleander poisoning. By R. Day, M. B., 127.
 Case of melena. By B. B. Chatterjee, L. C. M. S., 216.
 Case of parametritis: Recovery. By Rai Pate Ram Bahadur, C. M. S., 286.
 Cases of serious penetrating wounds of the chest and neck. Recovery. By Choithram Shewakram, C. M. S., 278.
 Case of lymphadenoma. Hodgkin's disease in a native. By Surgn.-Capt. J. Chaytor-White, M. D., 313.
 Case of placenta previa. By Adhar Chundra Mitra, C. M. S., 321.
 Castor seed confection. A case of poisonous symptoms from. Recovery: By E. Condon, I. M. S., 47.
 Carbolic acid used internally in gonorrhoea, 20.
 Carbolic acid treatment of malarial fevers. By Surgn. Capt. C. A. Nanjaba, L. M. S., 118.
 Calcutta. Sanitation of, 181.
 Calcutta sanitation. Theory versus practice, 20.
 Calcutta death-rate as compared with other cities, 20.
 Calcutta, Insanitary, 99.
 Calcutta. Insanitary, 137.
 Calcutta frauds and quacks, 137.
 Calcutta. Infantile scurvy in. By Prandhan Bose, M. B., 350.
 Calcutta Independent Medical College, 403.
 Calcutta Medical School, Sir Charles Elliot at the, 420.
 Calcutta Medical College improvements, 428.
 Carcinomata, endocarditis and pericarditis with effusion, accidental tapping of right ventricle after apparent death, Recovery, 23.
 Cardiac rupture. Post-mortem notes of a case of. By Asst. Surgn. J. J. Srinivasaagum Pillay, 89.
 Cardiac dyspnea, 103.
 Cataract in your own eye. How to see, 24.
 Cataract. Some modifications in the usual method of extracting senile cataract. By Dr. B. H. Nannavarty, 119.
 Cataract. A new operation for. By Rai Bahadur Meher Chand, L. M. S., 380.
 Cats and diphtheria, 185.
 Catgut sterilized, 142.
 Catheter versus the Hand, 141.
 Catheterization of the male ureter, 104.
 Catarrh caused by pot. iodide treated with Belladonna, 304.
 Catarrh of gall ducts, 338.
 Castration. Double, 266.
 Care of the teeth, 269.
 Care of the aged, 368.
 Calcium chloride in snake bite, 191.
 Calculus in the Fallopian tube, 302.
 Cancer transmitted from man to animals, 104.
 Cancer hereditary, 140.
 Cancer serum therapy, 369.
 Cannabis Indica, 108.
 Cannabis for itching, 304.
 Candidate nurse: what she should think of, 329.
 Causes of the diseases of women, 182.
 Causes of ill health of Hindu women and children. By Hari Kall Sen, 39.
 Causes of sexual debility in the male, 299.
 Cause of the local profession, 371.
 Cellular therapy and significance of fever in children, 181.
 Celotomy be performed in the treatment of puerperal sepsis, When shall, 62.
 Certificate. How two Presidency Surgeons countersigned a private physician's, 54.
 Certificates. The hobby of countersigning, 58.
 Certificate of membership in the Indian Medical Association, 100.
 Certificates of private physicians in Courts of law and the Government, 134.
 Cerebral tumour successfully removed, 430.
 Cerebral apoplexy. Temperature in, 333.
 Cerebro-spinal meningitis. By Surgn.-Capt. F. Hehir, M. D., 248.
 Cerebro-spinal fever. By Surgn.-Major Jas. Moorhead, 240.
 Central Provinces of India. Death by wild animals in the, 101.
 Ceylon medical work and medical administration, 426.

- Charity organization and medicine, 18.
 Charity. Medical, 99.
 Charitable dispensaries in Bengal, 135.
 Character. Elements of a good professional, 427.
 Chancres. Seat of, 272.
 Chancroids healed in from one to seven days by acetanilid, 334.
 Chest. Examination of the, 185.
 Cheese a carrier of disease, 232.
 Chemical Examiners. Infallible? Are 237.
 Chemistry of cleanliness, 483.
 Chloroform administration in some difficult cases, 33.
 Chloroform administered in labour, 98.
 Chloroform fatalities in India, 136.
 Chloroform. Fear in anaesthesia by, 395.
 Chloroxyline as a preparation of prussic acid, 20.
 Chloral in hæmoptysis, 370.
 Chloral in ear-ache, 431.
 Chloral hydrate, 484.
 Cholera hæmatozoon, 36.
 Cholera. Quinine in, 195.
 Cholera treatment, 37.
 Cholera outbreak in the Dinajpur Jail, 66.
 Cholera an acute specific fever. By Surgn-Capt. Patrick Hehir 73.
 Cholera. Quinine in. By Surgn. Capt. P. Hehir, M.D. 115.
 Cholera. A typical epidemic of. By D. Morrison, 115.
 Cholera and Life Insurance, 133.
 Cholera studies. Recent, 140.
 Cholera. Immunisation against, 267.
 Cholera rules, 394.
 Cholera mixture, Squibb's, 403.
 Cholera. Is there a better remedy for, 425.
 Chronic rheumatism micro-organisms, 144.
 Chronic rheumatism. For the pains of, 146.
 Chronic Cyanosis. The blood in, 231.
 Chronic inebriety from a medico-legal point of view, 259.
 Chronic constipation treated without medicine, 333.
 Chronic seminal vesiculitis, 333.
 Chronic gonorrhoea and marriage, 337.
 Chronic diarrhoea and dysentery, 403.
 Chronic nephritis treatment, 431.
 Cholecystotomy. New method of, 230.
 Children. Internal antiseptic in, 23.
 Children. Vaginitis in, 25.
 Children. Diagnosis of tuberculosis in, 141.
 Children. Biliary cirrhosis in, 299.
 Children with biliary cirrhosis, 394.
 Children's teeth. Diseases of. By R. Denison Pectley, 405.
 Children in the habit of dirt-eating, 429.
 Childhood. Neuroses of, 227.
 Chino-Japanese war, Medical heroism in the, 203.
 Civil employ. Seconding of men in, 151.
 Civil attendants not soldiers, 358.
 Civil Apothecaries, 372.
 Civil Surgeoncies in the Hills, 428.
 Circular amputation for comminuted fracture of the shaft of the tibia: Recovery. By Edward E. Balm, C.M.S., 417.
 Citizen. Physician as a, 262.

Original Articles.

THE VAGARIES OF NEUROMYTHESIA,
ILLUSTRATED BY THREE CASES.By SURGEON-CAPTAIN PATRICK HEHR, M.D.,
F.R.S.E., F.R.S.S.E., D.P.H. (Cantab).*Lecturer on Pathology and Clinical Medicine, His
Highness the Nizam's Medical School, Hyderabad.*

THE multiplicity of morbid phenomena which may be generated by those affected with nervous mimicry is proverbial. And whilst a large number of the cases possess certain characters in common, we occasionally come across cases totally distinct from all ordinary hysterical manifestations. Such was the case in the three following instances of neuromimesia.

1. *Forash Bhi*, female, *æt.* 32 years, Mahomedan, married 12 years, came under observation on the 28th March 1894, suffering from severe dyspnoea, with a "floating tumour" in the abdomen, violent palpitation, and occasional epileptiform convulsive seizures, lasting from a few minutes to half an hour, with great mental excitement, alternating with depression during the intervals.

The history of case is as follows:—About five years ago irregular menstruation began, from which time the symptoms above enumerated commenced. She had been under many *hakims* and physicians, both Unani and others, during that period, and every one appears to have diagnosed the case differently. This is the first time, however, she was placed under the systematic treatment of a European physician. The most varied forms of treatment had necessarily been employed, and when I began giving her valerianates, asafoetida, and other antispasmodics of that class, she at once stated that these had been already given her repeatedly without effect.

For about seven years she was obliged to live apart from her husband, whose occupation, that of Revenue Settlement Officer, necessitated his wandering about the country for several months every year. During that time she used to have constant quarrels with her husband's relations, with whom she dwelt.

Present condition.—The patient is a highly nervous, excitable woman, fairly well proportioned, but now somewhat emaciated; she is exceedingly intelligent, and is able to describe her own symptoms and sensations with clearness and accuracy. I saw her for the first time when she was suffering from an attack of the dyspnoea mentioned above.

It was not a breathlessness for want of air, but a curious abrupt stoppage of inspiration, similar to what one finds in pleurisy. In addition to this, after every four or five respirations the left half of the diaphragm would contract suddenly, and give rise to a stabbing or shooting pain, which she stated, began in the abdomen on the left side, and passed up through the chest to the left shoulder, and would then disappear till the next contraction began. She stated that she had also the sensation of the presence of a ball which would rise from about the position of the umbilicus and proceed upwards, but remain in the chest about

the middle of the sternum, and appear to compress the structures in the upper part of the thoracic cavity. She explains that before the epistaltic waves come up, this ball ascends to the throat and threatens to suffocate her, and that at that moment she becomes senseless.

There is a peculiar soft swelling in the infra-scapular regions on the left side, which is highly elastic, red on the surface, and painless, and appears to be in the subcutaneous structures. Examination of the chest reveals nothing abnormal as regards the lungs, but the heart's action is excitable (120 per minute). There is dilatation of the left ventricle, but all the sounds are clear and distinct. There is loss of sensation on the left side of the body, but this alternates with hyperæsthesia. BROWN-SQUARED'S phenomenon of metalo-therapeutic pressure over the left ovary, sets up the greatest distress, ending in the production of an hysterio-epileptic attack. There is what appears to be a floating left kidney in the abdomen, the position of which may be altered by palpation from the left iliac fossa to the left hypochondrium. This organ is excessively sensitive. The patient states that she has suffered from dyspepsia "all her life," but that it gets much worse every fortnight or so. Her bowels are very irregular, but usually constipated; sometimes she goes two or three days without passing an evacuation. One of the most peculiar features of the case is that she voids urine only once a day, every morning on getting up, when from 10 to 15 ounces are discharged. This urine is of high specific gravity (1085), high color, and contains an abundance of oxalic acid crystals, but no albumen or sugar.

The temperature is normal, but she had an attack of ague about a week ago, and has been subject to recurrence of the quotidian form of this fever for years.

This first examination of the patient appeared to exhaust her considerably, and I was obliged to relinquish it, before a complete investigation was made.

The liver functions are normal. The skin is now dry, but she states that once or oftener every day she sweats profusely on the left side, and that she is almost always obliged to lie on the back, because lying on either side gives her great pain and distress.

The attitude adopted by the relations was one of great anxiety and solicitude on the patient's account, which they made no attempt at disguising. Indeed the husband would every few minutes during my visit yield to bursts of overwhelming grief, which the relations, including his wife, in turn, would attempt to appease, but he, like his wife, would appear to be inconsolable. This lasting a few minutes, the wife would chime in, then the relations, the *lost ensemble* of this small tragedy, forming the most ridiculous scene conceivable. The cause of the perpetuation of the patient's state became at once evident, and the line of treatment to be followed, equally apparent.

I requested the relations to send for me at once when an attack of hysterio-epilepsy manifested itself, which they did the next evening. On entering, I found the patient stretched out in the crucifixion attitude, lying obliquely across the bed, quite unconscious, the body arched and resting on the occiput and sacrum, occiput boring the pillow. The hands were clenched, toes and legs turned inwards, the eyeballs turned upwards and

inwards, but after a while regular nystagmus followed. The patient bit the tongue in several places, and in the early part of the struggle for breath, tore open her jacket. There could be no doubt but that the attack was genuine and the patient's state serious, but by no means dangerous.

She believed herself to be completely paralysed, and that she could not move from the recumbent posture, which she had now retained for the last five months. There was thus, apparently, to those who did not understand her state, abundant cause for alarm. Although we attempted to reason with the husband and relations that the patient would get well, they looked incredulous. The only condition I imposed was that they should do exactly as I advised.

I laid considerable emphasis on the necessity of her removal to a strange place, and that all her relations, except the husband, be relinquished for the time being. It took many days to induce them to do this; but, at last believing the case to one requiring desperate measures, they permitted her removal. In the meantime, I was soon able to gain the husband's confidence; and being an intelligent man, he readily recognised the theory of the treatment. I had also partly acquired the patient's confidence, although it was evident that there was a lingering suspicion in her mind as to what was to take place, and that she had only a very partial belief in my treatment; for, as she expressed it, "if all our Unani *hakims* have failed, how is it possible for you to cure me?" Eventually results proved the reverse, and as she was improving rapidly, she was eventually satisfied that she could be cured, and this came about in a very curious way related below.

After observing the phenomena of this first fit of hystero-epilepsy, I saw that active agents would be necessary, and we dosed her with enormous quantities of three remedies—mixed bromides, nitro-glycerine and apomorphine.

She never had another real attack of hystero-epilepsy. I asked them to always send for me when an attack came on, and as they had brought the patient to within 100 yards of my quarters, I was able to get there at once. On the third day after the attack just described, I was hurriedly sent for, and on seeing her it was at once evident that the "fit" was a false alarm—that the patient was "acting" a fit for her relations' delectation. I said so (in her hearing), and uttered a great many severe things, whilst I was preparing (in her presence) a galvanic battery with which to electrify her. I also sent for a large *ghurrah* of water, but before either of these were ready, the patient relaxed her efforts, which had been very vigorous. This "fit" lasted 28 minutes. I explained to those around that this was only a very minor fit, when they said: "How can it be so? Feel how she is sweating, and see how flushed her face is!" I said to her husband, "you use your dumb bells for half an hour continuously and see if you will not be in the same state. This applied to their reason, and curiously enough, to the patient's also, who seeing that "the game was up," never created another attack of this kind.

The patient continued to pass water once a day only, and the curious sporadic condition of the left side of the diaphragm went on without interruption.

I could not make out what the swelling over the back was, nor do I know to this moment, whether it may have been a localised vasomotor paresis, with a certain amount of infiltration of serum and white cells. That it was not a curious condition was shewn by its entire disappearance. This swelling relieved, the spasm of the left half of diaphragm; the dyspnoea, &c., would have led one to surmise that a diaphragmatic pleurisy with effusion, or even an empyema had developed, but there was no pyrexia, nor any physical signs of effusion, and all the other indications of pleural or pulmonary disease were absent.

The strangest part of this is that the swelling behind, like the unilateral spasm of the diaphragm, entirely disappeared and re-appeared in the most fickle way, but not by any means always. One was forced to believe it to be unilateral spasm of the left half of the diaphragm. With each contraction of the diaphragm there was a peculiar noise, which was heard best on the left side of the chest wall in front, but which was altogether unlike hiccup; the physical signs of diaphragmatic pleurisy and pyrexia were absent. As a matter of fact, we can conceive such a curious state occurring only in a case of neuromyositis.

Regarding the micturition once a day only, (and that every morning at 10 o'clock, when only about 10 to 15 ounces passed) we apprehend that some deception or trickery, similar to that which these patients have been known to perpetrate in connection with the production of the so-called "paradoxical pyrexias" by friction of the bulb of the thermometer placed in one of the axillae. I had the patient carefully watched, but no such deception regarding this peculiar phenomenon was discovered. She could also produce (apparently at will), the most extensive localised swellings all over the abdomen, so that until one had become acquainted with the very high degree of neuromyositis present, one marvelled at the hypertrophy of liver to-day which was gone to-morrow, the same condition of the spleen next day, or an enormous dilatation of the stomach, and so on, all equally evanescent. Indeed, she could develop abdominal tumours at will in almost in any position.

I omitted to mention above that there was perpetual nausea and anorexia, but on two occasions only was there actual vomiting. There was comparatively little cough. Being a *goolia* woman, she would not allow me to examine the chest properly, but when they thought danger to be present, permitted a complete examination. I noticed then that there was a most peculiar swelling over the left breast also. It was circular, 6 inches in diameter, and 1½ inches deep, had a soft semi-fluctuating feel, elastic, and pulsating, but the latter was probably due to the diffuse undulating impulses of the dilated left heart and possibly due, as the other one, to local vasomotor paralysis, with perhaps a small amount of oedema from the turgescence.

The thyroid gland was not enlarged, nor was there any uterine disorder. As previously remarked, Brown-Sequard's metallo-therapeutic phenomenon was well illustrated. It would throw her into a peculiar cataleptic state, from which a whiff of amyl nitrite resuscitated her.

The great value of preparations of valerian and acafatida, nitroglycerine solution, bromides, and anti-spasmodics generally, all shewed a well marked hysterical element.

2. The second case presented symptoms almost as peculiar as those of the first, but in this instance the patient would lapse into a true cataleptic condition after a prolonged and well-marked fit of hystero-epilepsy. This history is interesting.

M. B., a Mahomedan lady, began to suffer from these attacks about seven months ago, and has had five in all. The first occurred two days after an accident. She fell in the dark from the basement of her house, which was three feet in height. Except a little bruising of the right lip, no injury was sustained. She was, however, as in case No. 1, alternately depressed and agitated during these two days, and indulged in out-bursts of crying every now and then, which culminated in the convulsive seizure above named. This attack and the three following were designated "hysterical fits," and in the main, this term indicated the predominating factor in the case. We, however, depreciate the use of such terms by scientific medical men, especially in the hearing of non-professional people. If an appellation has to be given to such conditions to satisfy either the relations or the patient, we much prefer that of "nervous mummery," the literal meaning of the term *neuromyrmia*. Highly irritable or nervous women amongst Europeans would not make the subject of "nervous mummery" one to be talked about, sympathised with, or boasted of, whilst they will entertain no such reluctance in making the subject of "hysteria" one of conversation, when that term has been employed in the diagnosis, although both conditions are, of course, identical. Hence the influence of even the name given to a disease in the case of females who suffer from this unstable condition of nervous tension. We see practically the same thing in the analogue of *neuromyrmia* in the male, viz., *hypochondriasis*.

We saw this second patient for the first time during the fifth attack. She had been ill for three days, and various remedies had been employed in the treatment. When we saw her, she was rigidly stretched out in the crucifixion attitude, the neck arched, the hands forming clenched, the face pale, the pulse small and frequent. The breathing was somewhat shallow, but every few minutes she would take a long deep inspiration. The attacks would last about 20 minutes, and after every one of them she would lapse into a cataleptic condition, sometimes with the eyes fairly closed, at others, immovably fixed on the ceiling. Here also there was a peculiarity in regard to the urinary discharge. Whilst the attack lasted, she would not void urine more than twice a day, and then only in small quantities; but as soon as it passed off, she would discharge no less than 8 pints a day of the usual neuromymetic character, pale, limpid, of low specific gravity, with a relatively small amount of urea, but absolutely, considerably larger than in health.

In this case the pulse instead of becoming weaker as the attack was prolonged, it became harder, and although nitrites of sodium or nitroglycerine or a few whiffs of nitrite of amyl would relax the tension, this effect was transient, and whilst it lasted, the heart would be thrown into the most violent palpitation. The patient remained in this state for 36 hours, after I took over charge of her case. The whole phenomena ceased abruptly, whilst we were giving her the usual dose of five minims of nitrite of amyl on a handkerchief. Suddenly she appeared to wake up out

of a long sleep with a sort of start; she appeared considerably prostrated, but spoke rationally, asked to see her two children, took some stimulant mixture and chicken broth, and then lapsed into a sleep which lasted from 5 P.M. to 4 A.M., gradually returning to health.

The third case is also that of a Mahomedan married woman, who is the mother of three children, the last being four years old. When before her marriage, she suffered almost monthly from dysmenorrhoea and scantiness of discharge. The history briefly is—

3. M. M., *act.* 22 years, has been married 5 years, but joined her husband only about 2 years ago.

This case was one of a very unfortunate character, being the only child of doting parents, she had acquired a very violent temper which they early did not check. The temper used to last from 24 to 72 hours, and at the end of this time she would lapse into the neuromymetic state. Her temper was exaggerated by various domestic circumstances into which we need not here enter.

The convulsive seizures began with violent attacks of epileptiform convulsions, during which the patient was semiconscious. The attacks were intentional, and during the intervals she would be possessed of destructive tendencies, especially in the presence of her husband.*

It was quite evident that this was a perfectly different case to the two preceding ones, and required a different line of treatment altogether. The patient could control the seizures, as a rule, and whenever it suited her morbid imagination she would develop an attack for the delectation and anxiety of her relations. This became evident very early in the management of the case, and although the line of treatment adopted was for a long time only tolerated by her relations, I was able to convince them eventually by two complete demonstrations, that the patient was only playing with their sympathies and wanting to arouse their anxiety. I do not make these statements with the view to shewing that there is any vice in these neuromymetisms—far from it. Their sufferings are as real to them as are those of the most severe cases of tetanus, or "Jacksonian (partial) epilepsy." My special object is to shew that a great deal of discrimination and much experience are needed to understand these cases thoroughly, and that no routine system of treatment can be adopted. In two of the three cases quoted above, "harsh measures" were required, as a rule; but even in these two there were times when such means would create an attack. In the other, a calumniate and re-assuring line of treatment was required, whilst in the case of *neuromyrmia*, alluded to in the foot-note, anything approaching severity or harshness would not only have been barbarously cruel, but would have lost for the physician the patient's and the relations' confidence, by pointing to the fact that he did not comprehend the nature of the highly complex and morbid state of mental and bodily functions under which the patient was suffering.

* It was my intention to have contributed another exceedingly interesting case, in which there was apparently suspended animation for several consecutive hours, whilst the pulse would disappear from the wrist, and the first sound at the apex become almost inaudible, followed at the end of that time by Cheyne-Stokes respiration, the onset of which was always a sign of return to consciousness. There are many other very strange factors connected with that case, but the notes regarding it are with my friend, Dr. MIRZA KAHIM KHAN, Inspector of Diapentasis of His Highness the Nizam's Domains, who is on tour. We hope in a future issue to supplement the present paper with the particulars of that case also, which in every respect appears to us to be one of the most interesting instances of "suspended animation," so called, that has been recorded in recent times, whilst there was distinct response to the conjunctival reflex; there was also nystargism, another curious feature of the case.

REPORT OF SURGICAL OPERATIONS PERFORMED AND MEDICAL WORK DONE DURING 1894-95 IN THE JUNAGADH STATE HOSPITAL.

By T. M. SHAH,

Chief Medical Officer, Junagadh.

THE SURGICAL OPERATIONS performed during the past year in all institutes of the State were 2,855—358 being major and 2,497 minor. Most of the major operations have been performed at the Junagadh Hospital.

The prevalent diseases of the year were:—malarial fevers, diarrhoea, dysentery, eye diseases, nervous affections, bronchitis, injuries, intestinal worms, rheumatic affections, diseases of the urinary system, and of the cellulo-cutaneous and cutaneous systems.

A summary of a few interesting cases treated at this hospital is subjoined:—

Cataracts.—101 patients were admitted for cataract and 144 cataract extractions were performed, of which 115 were successful and 27 unsuccessful; 2 patients absented.

Out of the 144 extractions, 79 were on the right eye and 65 on the left eye.

Of the 99 patients operated upon, 68 were males, 29 females, and 2 children.

I have noticed in a few instances that cataract ripens and vision is reduced to mere perception of light, further changes then take place and vision improves and the patient is able to discern large objects and can count fingers. This is very likely due to the liquefaction of the cortex.

Children in the same family getting cataract after fever attacks.—MOHAN KHANDAR, aged 5 years, has both eyes cataractous since the last 18 months, after an attack of continued fever for 6 days.

22nd April 1894.—Chloroform administered, incisions were made in the cornea, and soft lenticular matter withdrawn, some capsular opacity persisted in the left eye. Discharged with fair vision.

II. JIVI KRIMDAS is the sister of the above-mentioned patient. Sight of both eyes began to be impaired 4 years ago after an attack of fever.

Left cataract has matured, (right eye not so), by which she is able to see from the inner margin of the pupil, and is able to go out.

23rd April 1894.—Linear operation performed on the left eye, iris excised and the semi-solid lens removed; some capsular opacity persisted; discharged with fairly good vision.

On 20th February 1895.—Linear extraction performed on the right eye after maturation of cataract; capsular cataract formed, but has good vision through a perforation in the capsule.

III. DULEHA UDESHANKER, set. 7 years. Infantile cataract of both eyes with marked nystagmus.

8th July.—Linear operation performed on both eyes; capsular opacity persisted; vision did not materially improve.

Glaucoma.—Numerous cases of glaucoma, both among males and females, are noticed among out-patients. Most

of them are cases of the complete form, beyond the reach of remedy. Many are of a chronic variety, which are inamenable to treatment. Few cases are fit for iridectomy, and they are not very satisfactory in their results.

Trichiasis.—Thirty-three cases as in-patients and several others as out-patients were treated, most of whom were women. Cooking together with frequent weeping for the dead, renders them more liable to trichiasis than men. For every man there are 6 women suffering from this distressing disease. Some patients resort for treatment early, while others turn up only when the cornea has lost all its transparency. In elderly women and widows, the ciliary edges are scalped, in young and married women, ABEL'S operation is attended with satisfactory results.

Hypertrophy of conjunctiva.—A lad, FOOLCHAND, aged 20 years, suffered from hyperplasia of conjunctival tissue. His upper eyelid drooped and the ocular and palpebral conjunctivae were very much thickened; conjunctivae were excised before he was relieved.

Urinary calculi.—Eighty-two cases were admitted; 2 absented and 80 were operated upon; 2 were urethral and 78 vesical stones. Among the 80, 43 were males, 2 females, 35 children. Among the 78 vesical stones, 62 litholapaxy, 7 perineal litholapaxy, and 9 lithotomy operations were performed. Of the 62 litholapaxies, 58 recovered and 4 died; all the lithotomy cases recovered. Among the 62 litholapaxy cases, 24 were male children and 1 female child. The ages of the children varied from 2 to 12 years, their average age being 5 years, and they all recovered. There were 37 males of whom 4 died and 33 recovered. Of the 7 perineal litholapaxies, 5 were children and 2 males, of whom 1 died and 6 recovered. Of the 9 lithotomy cases, 3 were males, 1 female and 5 children.

Lithotomies and perineal litholapaxies were performed only when for some reason regular litholapaxy was inadmissible.

Of the 2 urethral stone cases, 1 was a male and the other a female child. In the male, a small stone was lodged within the glans penis and was scooped out.

Urethral stone retention and extravasation of urine.—A child 4 years of age had a stone impacted in the prostatic portion of the urethra; for three days retention and extravasation of urine took place. On 17th February 1895 incisions were made over the hypogastrium, penis and scrotum, a catheter passed and urine withdrawn. The stone could not be dislodged either forward or backward, a staff was therefore passed, and the stone was thought to be pushed back into the bladder, which was then opened through the perineum, but the stone was not found in it. It remained in the urethra. It was then forcibly extracted per meatus urinarius. The perineal wound served as a direct passage for the urine, and the wounds over the hypogastrium, penis and scrotum, strange to say, healed up very rapidly, no tissues sloughing. The child was discharged cured on the 25th.

Among the 5 fatal cases of vesical calculi were:—I. VELA JIRAN, aged 18 years, a very unfavorable case. He was extremely emaciated, face was careworn with retching, there was disinclination for food, the urine was very ammoniacal, fetid and loaded with pus; the stone filled almost the entire vesical cavity; it was extremely hard,

white and marble-like in appearance, more than 2 inches in diameter. The blades of the lithotrite could not lock together without being hammered and as the lithotrite could not be freely manipulated on account of the size of the stone and contraction of the bladder, an opening was made through the perineum and the stone removed piecemeal. The total number of fragments collected, weighed 1,382 grains. The operation was performed on the 8th July 1894, and the patient died of exhaustion on the 11th.

On *post-mortem* the bladder was found contracted and hypertrophied. Both ureters were dilated and the kidneys degenerated.

II. DEOSHI MALA, aged 20 years, had a phosphatic stone in the bladder of 5 years' duration; urine strongly ammoniacal and loaded with albumen and mucus; stone was lodged in the neck of the bladder which appeared to be divided into two compartments. The stone was crushed on the 24th June 1894. Patient gradually sank and died on the 29th. His temperature not rising above 100°.

III. SAJAN ARJAN DHED, aged 50 years, had vesical calculus for 3 years. Stone was crushed on 1st March 1894, and the debris removed, weighed 274 grains. Patient died on the 8rd. On *post-mortem* examination the bladder was found to be sacculated and ruptured.

IV. KALA RAJA, aged 30, suffered from stone symptoms for 18 months. Litholapaxy performed on 29th August 1894; 13 drams of chloroform consumed. Hard stone, $\frac{1}{2}$ inch in diameter, crushed and 592 grains of debris removed. He died of peritonitis on the 30th.

V. NARAN RAMO, aged 40 years, vesical calculus of 2 years' standing. Stone was $1\frac{1}{2}$ inch in diameter, crushed on the 6th September 1894. While aspirating, the debris greatly blocked up the canula with fragments; it was withdrawn, cleared, and re-introduced. It missed the bladder; and the aspirator failed to bring out debris. Bladder was therefore opened from the perineum in order to afford free vent to urine and avert infiltration. However, peritonitis supervened and patient died on the 8th.

Thus of the 5 deaths among adults, 2 were due to rupture of bladder, and 3 to unfavorable conditions of the bladder and general ill health.

Interesting stone cases: sacculated condition of bladder.—MAVJI NARSI, aged 10, was subjected to stone operation. Lithotrite No. 5 was introduced but could not work well, as the stone seemed to be in the anterior cavity. Perineal incision was made, and on introducing the finger, the stone was found in one cavity and there was another smooth-lined cavity below and over the rectum.

This feeling of a sac or another cavity was also experienced in the case of SIMO HAGO, aged 12, who was operated on the 15th June 1894.

High temperatures no bar to stone operation.—RUBO RAM, aged 8½ years, had stone in the bladder and suffered fever on admission in March 1894. Temperature rose to 102° to 104° in the evening, but his father was bent upon having the stone removed at once. Litholapaxy was therefore performed on the 16th and the child discharged on the 22nd, quite well.

Recurring stone.—NATHA MULA was admitted for recurring stone on 8th May 1893. Stone was removed by

perineal incision after crushing it into fragments with a lithotrite, as this small instrument that was passed per meatus could not crush it. On 4th May 1894, a recurring soft phosphatic stone was crushed and debris aspirated; bladder was chronically diseased. Discharged well on 15th.

Adherent stone.—JIVA GOVA, aged 80 years, suffered from stone which was adherent to the anterior wall of the bladder. Lithotrite could not therefore crush it completely. Perineal incision was made and the attached portion was detached by means of the finger and was then removed by forceps.

Fragment of stone undetected.—MUSA VELA, aged 60 years, was subjected to litholapaxy on 28th October 1894, and the operation completed under the belief that the bladder was emptied of all fragments, but the patient continued to complain of painful micturition, and on 9th November, on examining the bladder, a fragment about $\frac{1}{2}$ inch in diameter was, strange to say, detected; it was then crushed and removed.

Stone perforating anterior wall of vagina.—RANI MULA, aged 40 years, was operated on 10th January 1895 for a recurrent stone. Litholapaxy was performed upon her 3 years ago; the stone could not be seized by a lithotrite, as it appeared to be adherent. On vaginal examination a spiculum of stone projected from the posterior wall of bladder just in front of the cervix; it was pushed back into the bladder and removed piece-meal per urethram.

Stricture of urethra.—Eight cases of urethral stricture were treated, 5 of them were by gradual dilatation with catheter and 3 by operation.

I. In one case the urethral orifice was contracted in the stump of an amputated penis. In this instance the urethra was dissected out and left out in the perineum.

II. In the case of UMAR, WHEELHOUSE's operation was performed for resilient stricture, and a rubber catheter was retained in the urethral passage.

III. MULIBHAI, aged 20, suffered from traumatic stricture of the prostatic portion of the urethra. This stricture was impermeable. After a fall on the perineum 3 years ago, he got the stricture with incontinence of urine. The urine keeps constantly dribbling away without any distension of bladder.

This combination of impermeable traumatic stricture, with incontinence is very unique and rare. WHEELHOUSE's operation was performed and a rubber catheter retained in the bladder. Patient is still in hospital, stricture is relieved, and the incontinence has disappeared.

In one case, viz. that of AHMEDSHA, male 45 years, a perineal incision was made for chronic cystitis and rest afforded to the bladder. The urine was voided per perineal wound for several days and the patient was discharged well within a fortnight.

Seven cases of diabetes were treated mostly with codeia and opium. One patient, JAGOO, had administered daily, one pancreas with a little salt and black pepper for several days, but without any visible benefit.

Piles.—Two cases of bleeding piles were treated with injection of carbolic acid with very satisfactory results:—

I. KHASOZ, a young man, suffered from bleeding piles and prolapsus ani. He suffered from excessive bleeding,

and was very pale and debilitated. Four injections of carbolic acid into different piles relieved him of all symptoms, and his general health improved considerably.

II. POPAT D, a prisoner suffering from excessive bleeding piles. He had enlarged spleen, anæmia and general oedema of the body. His state of health was such that he could not get up or walk without dyspnoea.

Any operative measure was out of question. On examining the rectum two small piles were observed lying immediately above the verge of the anus; both were injected with carbolic acid. From that very day they ceased to bleed.

Prolapse of the anus and rectum, with or without bleeding, were treated (with marked benefit) by the injection of nitrate of silver into the rectum.

Elephantiasis Arabum.—GAGO MULA, aged 10 years, suffered from an elephantoid growth of the prepuce, scrotum and left lower limb. He had intermittent attacks of fever, together with inflammation of the above-mentioned parts. The penis was buried within the elongated prepuce, which was excised on 4th June. The scrotal skin was somewhat thickened and was studded over with miliary elevations. Irrespective of the inflammatory affection, fluid dribbled from the scrotum, and was at first mistaken for urinary fistula, but on careful examination, the fluid was found to be serum.

II. KRISHNAJI SHANKARAJI, aged 45, suffered from an elephantoid growth of the right leg and left forearm for 3 years. He had no inflammatory attacks of fever. Both the patients were treated for a period of about 2 months with the administration of cow's urine, sodii sulphocarbolis, juice of "Piludi," (night-shade, a native diuretic and cathartic) and the succulent aloe leaf without any benefit.

Spontaneous gangrene.—KANJI MANJI, aged 25 years, admitted 13th August 1894 with spontaneous gangrene of the left great toe; the soft parts had dropped off and the dead bone was projecting. Adjoining portion of the foot was swollen and painful. The distal portion of the right index finger had been mortifying for one year but dropped off a month ago. The great toe, 2nd and 3rd toes of the right foot mortified after a slight injury, 4 years ago.

15th September 1894.—Patient has been in hospital more than a month. His temperature varies daily between 98° in the morning and 101°·8 in the evening. He is losing flesh, has had prescribed quinine and tonics, poultice and dressing being applied locally, without any benefit. On the other hand, the gangrenous ulcer is spreading over the dorsum of the foot, the first metatarsal is exposed and all the remaining four toes have ulcerated at their base. Pulse at the left wrist and axilla is fairly well marked, but there is no pulse at the right wrist, and a very faint one at the right axilla. Pulsations in both femorals well marked.

The patient had been suffering from this dry and slow gangrene since the last seventeen months, and also losing ground by constant fever; and as there was no line of demarcation, SYME'S operation was performed on 17th September 1894. On removal of the foot, there was no bleeding and no vessels could be discerned; the tourniquet on the thigh was gradually loosened, and at last totally removed, without a single vessel spurting. A short while after, there appeared some oozing, but the vessels were secured, and

sutures and dressings applied. The subsequent progress was very tardy and unsatisfactory. The healed flap died and an abscess formed on the lower part of the leg. Temperature fluctuated between 99° and 100°, at last the stump cicatrized completely, and the patient was discharged cured, on the 29th November 1894. The vessels of the affected foot were degenerated and occluded, and therefore gave rise to the gangrene.

II. DOBA DAVOD, aged 50, admitted on the 8th June 1894 with gangrene of the terminal phalanges of the middle and index fingers of the left hand. He was treated with tonics and ordinary dressings; the healed tissues gradually separated, and he was discharged cured.

JUMASHA KHASADIA, aged 40, a beggar, received a prick from a thorn 4 years ago, which was followed by gangrene of the great toe of the right foot, which gradually increased and SYME'S operation was performed; he was sent home well.

The great toe of the left foot became gangrenous after a slight injury; it was removed with its tarsal bone two years back and he was discharged cured. Lately he was admitted for gangrene of the second toe of the left foot. His general health is fairly good, but he is liable to gangrenous inflammation on the slightest injury.

(To be continued.)

NASA FEVER.

BY LAWRENCE FERNANDEZ, M.D., L.R.C.P. & S.
(Edin.), L.S.A. (Lond.), L.M. (Rot.)

Calcutta.

(Continued from page 364, Vol. VIII.)

Pathology.—There is a congestion of the mucous membrane of the nose and frontal sinuses. The mucous membrane is slightly raised, but there is no inflammation. Following the congestion there is slight catarrh. Often on pressure there is a doughy feeling, but suppuration never occurs. There is no tissue change in the mucous membrane, which, however, assumes an hypertrophied appearance after repeated attacks. The blood which escapes consequent on a method of treatment commonly practised, (detailed below) and which gives immediate relief, is of a darkish color and poor in plasma. Examination under the microscope of the blood shews an increase in the number of colorless corpuscles, the red bodies presenting a crenated appearance.

Treatment.—Quinine and arsenic have no effect on the disease. Opium relieves the pain in the neck, back, etc. Tartar emetic in doses to induce diaphoresis has not with good results, and I know of one case where both local and internal treatment failed to give relief, in which this drug was of the greatest service. A brisk saline purgative is all that is needed in the simpler cases. The usual method of treatment, and that which gives the most relief, is depletion, which is done either by (1) (as the natives do it), two bundles of *dhoo* grass introduced into the nostrils, over which friction and outside pressure are applied against the septum; (2) by a few pricks of a needle; or (3) by a few punctures with a bleeding lancet. A small quantity of blood escapes and the sufferer is restored in a few hours, to perfect health. This plan of treatment,

however, is only palliative, and the great objection to it is, that if frequently done, it induces an hypertrophied condition of the mucous membrane, but which has no effect in lessening the efficiency of similar treatment in future. Very often it is not safe to follow this plan, for although it is generally followed by relief, and by a subsidence of the accompanying fever, yet in some instances the congestion, with all its train of symptoms, recurs. The local application of astringents, such as a solution of tannic acid, or a 10 per cent. watery solution of cocaine, has given good results in the hands of many practitioners. The application of *akanda* juice (*Calotropis Gigantea*) to the mucous membrane also gives relief. The febrile symptoms must be treated according to indications.

The plan of treatment I have adopted in cases which have come under my notice, of a few Europeans, and a number of Natives, is as follows:—A brisk purgative, injection of cold water, cold affusion (injection of iced water up the nostrils), two or three times a day, with diaphoretics internally.

This line of treatment has invariably given me good results. Fever and nasal affection passing off within three or four days. In a few instances, however, high fever followed the subsidence of the congestion, and even delirium in one case.

Conclusion.—Such is the brief history of a disease which, as I have said, although very common in this province, has not yet received a place in medical literature. That it is well known to practitioners of this country there is no doubt. The *kobirajes* and *hakims* know all about it, and they apparently have been quite conversant with its existence for many hundred years. In one of the oldest Tantras there is found detailed, in a discourse on fevers by SIVA, explaining the same to his wife PARVATI, as follows:—

PARVATI says:—"Oh MAHADEVA! thou perceiver of past, present, and future, Oh thou merciful God of gods! thou who knowest all, tell me all about fevers; Oh! for the benefit of men tell me."

SIVA: "Oh, DEVI! hear the different forms of fever. A knowledge of them makes an adept physician—Fever is divided into two varieties: (1) that which begins with rigor; and (2) that which begins with heat. These again are divided into four, where they terminate by collapse and delirium. These four varieties are sub-divided into twelve other forms produced by impurities of mucus, bile, and phlegm."

"That which begins with cold (rigor) is divided into non-eruptive and eruptive fevers.

"The non-eruptives are periodics:—Daily, quotidian, tertian, and quartan agues.

"The eruptives are:—The typhoid, the plague, *nasha jashar*, and the epidemic of small-pox.

SIVA continuing says:—"Oh DEVI! *Nasha jashar* shews itself at the nostrils, they become occluded, the pulse becomes irregular (like the leaps of a frog), temperature increases, there is severe headache, soreness of the eyes, constipation, dysuria, and delirium. The mouth palate, throat, and lips are dry; there is a running from the nostrils, pain in the back, flanks, and abdomen.

After 15 days the severity subsides, but the first three days are the worst through which the patient passes when the disease reaches its crisis, and the patient either passes into convalescence or the disease ends fatally."

Again, in the *Ayur Veda* it is stated, that "*nasha jashar* originates from disorder of the bile in a phlegmatic constitution. The swelling in the nose is like the flake of an onion, and it appears either in one or both nostrils. It is always attended with more or less fever, and pain all over the body, especially in the nape of the neck and forehead. Scarification is the treatment."

THE VALUE OF APOMORPHIA AS AN ANTISPASMODIC.

BY EDWARD BALM,

District Surgeon, Parbhari, Hyderabad.

APOMORPHIA was introduced in the Afzulgunj Hospital, Hyderabad, by DR. LAWRIE in the treatment of tetanus on the suggestion of DR. BOMFORD of Calcutta. DR. LAWRIE used to administer it in doses of $\frac{1}{16}$ to $\frac{1}{4}$ grain hypodermically twice or three times a day, and the results were not disappointing.

Last year, when I took charge of this hospital, I had a unique and distressing case of hiccup in a man 50 years old. He suffered from it for about 6 months, and the acts numbered 30 to 40 per minute. He had been a well-built man, but was reduced to a skeleton, and the sight of food was most loathsome to him. He tried a lot of native medicines without any relief, and my predecessor prescribed for him almost all the drugs of the pharmacopoeia without the slightest good. I subsequently tried atropia, morphine by the mouth and subcutaneously, bromide of potassium, camphor, chloroform, emetics, mustard plaster over the region of the diaphragm, and a host of others without the least good.

I then thought that as hiccup is a symptom caused by a spasm of the diaphragm, I have evidently a spasmodic disease to deal with, I therefore gave him $\frac{1}{4}$ grain of apomorphia dissolved in 107 parts of water hypodermically. In less than 3 minutes the symptom subsided, and in 5 minutes more, he vomited. He was not troubled with the symptom for two days, but the third day he came again to hospital with it—it was less troublesome than before. I gave him $\frac{1}{4}$ grain of apomorphia more, hypodermically. The symptom subsided in about the same time, and there was retching and vomiting the whole day, but the hiccup never recurred.

I was not able to find out the cause beyond that he was a great smoker of tobacco.

Hiccup as a minor symptom, is familiar to all. Whenever I get it, I generally take a long breath and "hold it in," repeating this at frequent intervals, (so as to cause a regular and uniform pressure on the spasmodic diaphragm,) with excellent results. It would be interesting to know if this simple remedy has been tried by anybody before.

I have also tried apomorphia in a very bad case of hysteria, in a young woman, that defied every other treatment, also in cases of asthma, and in all these instances it afforded temporary relief.

THE RADICAL CURE OF HERNIA INGUINALIS PERFORMED AT THE PONDICHERRY HOSPITAL.*

BY HENRY GALLAY,

Surgeon-Major for the Colonies.

SINCE the last two years that we have been in charge of the medical service at Pondicherry, we have performed in the hospital 36 times, the radical cure of hernia inguinalis.

Number.—The number of operated cases is only 36, because twice we have had to operate on hernia of the two sides in the same man.

The operations have been done 31 times on the right side and 7 times on the left.

Complications.—Twelve times our hernia cases have been found complicated and our surgical operations aggravated owing to the necessity of having to perform in the same meeting: Twice the amputation of a cancerous osticle; twice the radical cure of old hematoceles; eight times the radical cure of old and voluminous hydroceles; twice adhesions of the intestine with the hernia sac. It was impossible to extirpate these adhesions, and we were obliged to reduce the intestine and the sac from which. It was impossible to separate it. Three times we have noticed that the cecum came down into the scrotum. Once the cecum was accompanied by the upper part of the colon and by a lump of epiploic fringe abnormally swelled; the lump weighed nearly 4 lbs. Another time we saw the cecum and the ileo-caecal appendiculum ruptured on the left side. Again on another occasion we found the hernia sac adhering to a greasy tissue 3 inches in thickness. Thus out of 36 operations, 18 were complicated, or 50 percent.

Failures.—Notwithstanding the above disadvantages we had but 4 fatal cases, that is 10½ per cent., which average is far from approaching that of the last statistics of BARKER, BASSINI or of LUCAS—CHAMPIONNIER, and still less the mortality obtained by other surgeons.

The cases of death have been:—

One by tetanus.—(The local hospital where we operate has formerly been the hearth of tetanus).

During the last year, although we have carried out upwards of 300 surgical operations, it was the first time that terrible infection occurred, and perhaps we would have as much right in accusing the tissues of our patient as the locality where we operate. The man was a farmer living in contact with the soil; perhaps the assistant in charge of the antiseptics had not sufficiently disinfected the surgery field.

On one occasion the hernia sac was doubled into a sort of wen from which it was impossible to extricate it, it was strangled by two pieces of catgut crossing each other and was then reduced; the thickness of the greasy tissue was no doubt such that a small artery was insufficiently strangled. A little stickiness was formed on the right side of the iliac pit, the hernia was then on the left, fever set in, and the patient succumbed after presenting the symptoms of peritonitis. When the corpse was opened, it was noticed that the neck of the sac, which was on the left side, had shifted after its reduction, to the right, and that,

around it, a little hemorrhage had taken place, which served as the starting point of the peritonitis.

The third case of death was due to prolonged suppuration: we had, on the same patient who was (infant and old, performed on the same day the radical cure for hernia inguinalis of the right side and an old hydrocele of the left. There was no serious accident on the side of the hernia.

On the side of the hydrocele, there was a collection of fluid in the lower part of the scrotum. The wound cicatrized by first intention, we were therefore surprised to find at the inferior and posterior part of the cords a large piece of tissue gangrenized, and the elimination of the slough caused a suppuration of long duration from which the patient succumbed on the 17th day of the operation.

The fourth and last case was that of an old man in whose scrotum we found not only the cecum, but the greater part of the large intestine with 4 lbs. of epiploic fringe abnormally swelled. The reduction of this mass of large intestine was very painful. Everything seemed to have taken place normally. In the evening, 12 hours after the operation, the patient was well. In the night, however, the stomach swelled with extreme rapidity and he succumbed to the symptoms of asphyxia, before we could be sent for.

The opening of the dead body was not permitted. I always thought that the reduced intestine, instead of being stretched out, must have rolled itself up, and that the loss of our patient must be imputed to strangulation by torsion.

As we have finished relating our failures, we will now proceed with our successes.

Successes.—Twelve times we have obtained the ideal result, that is to say, union by first intention, ablation of the sutures on the 8th day, complete cure on the 15th. By precaution the patients were kept in bed until the 30th day, when they left the hospital.

Twenty times the cicatrization has been delayed either because sometimes the sutures have cut the flesh; or because a little liquid had accumulated under the superficial sutures which it was necessary to allow to fill up the cavity which was formed for that purpose.

In two cases, we found the cord of the testicle swelled, with profound suppuration.

The operated cases kept in the hospital generally 45 days. Two stayed 48 days, and only two left on the 53rd day.

Therapeutic results.—Authors are willing to admit that relapses after the operations for hernia occur before the sixth month.

We have met 14 of our operated patients, whose surgical actions dated:—

| | | |
|---------------------|-----|------------|
| 29th December 1892 | ... | 21 months. |
| 25th August 1893 | ... | 13 " |
| 17th September 1893 | ... | 12 " |
| 6th November 1893 | ... | 10 " |
| 10th " | ... | 10 " |
| 24th " | ... | 10 " |

* A paper read before the Indian Medical Congress and sent to the Record for publication.

| | |
|-------------------|----------|
| 1st December 1893 | 9 months |
| 17th " | 9 " |
| 20th " | 9 " |
| 29th January 1894 | 7 " |
| 12th February " | 7 " |
| 23rd April 1894 | 6 " |
| 25th " | 6 " |

Among all, the recovery has kept up perfectly well.

Among all, the scar is soft, and the cord inguinalis free from adhesion.

And what makes the whole of these results interesting is that :

Among the operated patients, one happened to be an old weak looking man, sixty-one years of age, and with whom the cure of an ancient large-sized hernia has been completed by the excision of a cancerous testicle.

Having regained his plumpness and alertness, this old man, formerly an impotent, walks now easily since about two years.

The next were four sepoys, who after one month's rest, have, the first since thirteen months, the two others since ten months, resumed their military duties and bear all the hardships entailed.

There were three police peons of whom one patient was operated on the 20th December while he was a scholar ; he left the hospital to enlist himself as a sepoy, and since ten months is well enough to perform the military gymnastics and other exercises, and bears without difficulty the painful period of the young soldier's instruction.

Two were Europeans : one was a Doctor on board a steamer, he has since six months resumed his duty on board, and goes up and down the ladder, supports the necessary muscular efforts to struggle against the rolling and pitching, and that without wearing a truss.

The other one is a sort of vagabond, having lost all self-consideration, operated more than ten months ago for a hernia, which was about the size of a grown-up person's head. He again commenced his old existence of rower, living on the roads, wandering on foot from Cuddalore to Pondicherry, even extending his begging trips to Trichinopoly, without being tired or threatened with relapse.

Method employed.—In all cases, I made use of Bassini's process, which, as every Surgeon knows, consists in the reconstitution, by means of two whips of catgut, of the partitions of the channel inguinalis, in their full length, while the deep orifice of the channel retains just the width sufficient for the inguinalis cord to pass through.

Conclusions.—The therapeutic method I have just mentioned gives to the reconstituted abdominal partition perfect stability, allows the inguinalis channel to be free to let the cord pass through, and by shutting the deep opening of this channel, prevents all possibility of a relapse.

The busy and tiring existence which since the operation, our two European subjects, our four sepoys, three police peons and the young recruit have led, all confirm the conclusions which BASSINI himself, when publishing his surgical method, thus formulated ; viz :—

That, as soon as successfully operated for an inguinal hernia, when the reconstitution of the partition of the channel has been methodically made, the patient may be considered completely cured, he can go through the most trying profession, and no longer bear any bodily defect, on account of which he is usually rejected from the military profession, or exempted from the military service.

A MIRACLE OF PLACIDITY.

TEMPORARY LOCAL ANÆSTHESIA FROM HYDRATE OF CHLORAL.

By SURGEON-CAPTAIN PATRICK HENIR, M.D.,

F.R.S.E., F.R.C.S.E., D.P.M. (Camb.)

Lecturer on Pathology and Clinical Medicine,
His Highness the Nizam's Medical
School, Hyderabad.

WHEN chloral hydrate is taken continuously as a soporific for some days, it is well known that it is likely to be followed by a localised paralysis of sensibility, but such a result may follow upon a single dose ; and sometimes from a comparatively small dose.

During the last five weeks, three such cases have come under my observation. The first, a Hindoo male, *et.* 40 years, was suffering from a severe nervous shock, followed by insomnia. After two nights and days of complete sleeplessness, I was asked to prescribe for him. I gave 30 grains of bromide of potassium, combined with 20 of sulphonal, to be repeated every two hours, until sleep was induced. During the night he took 150 grains of the former, and 100 of the latter, without any effect, except a little drowsiness, which came on the next morning, and continued throughout the day. The same was repeated during the next, (that is, the fourth) night without producing even drowsiness. He had taken, therefore, 300 grains of bromide and 200 of sulphonal. On the fifth day, I prescribed 30-grain doses of chloral hydrate to be repeated every half hour, until sleep was produced, in the same way as we give the drug for rigidity of the *os uteri* during the first stage of labor. Three doses were ordered. The third dose had the desired effect of causing a sound normal sleep of seven hours. The next morning on waking, he found that the whole area supplied by the sensory fibres of the musculo-spiral nerve of both sides were paralysed. I was somewhat alarmed at this result, considering the large quantity of hypnotics he had consumed in the preceding three nights. The next night no sleeping draught was administered, and the sensibility of the parts returned, but he had no sleep. On the 7th night we again repeated the chloral with the same effect, although he had only taken two doses of 25 grains each, but the area of skin supplied by the ulnar nerves alone was anæsthetised. This wore off at about 4 P.M., and from that day the patient would not take any more hypnotics.

T. A. N., a stalwart man, in the enjoyment of sound health, was suddenly attacked with acute bronchitis of a severe type, followed by symptoms of bronchial asthma. The fits of coughing were purely spasmodic, and very violent, with no expectoration. I prescribed 15-grain doses of iodide of potassium with various expectorants and antispasmodics, but these failed to produce any decided effect on the violence of the cough. It became necessary to administer opiates. These also failed, and 8-grain doses of chloral hydrate were prescribed. The chloral successfully lessened the severity of the attacks of coughing, but the second dose produced a peculiar numbness of the whole of the outer aspect of the right foot and leg, and the outer part of the

cutaneous area supplied by the sensory spinal nerve. All possible points of compression of the nerve implicated were inquired into with negative results. My experience led me at once to recognise the cause and the evanescent nature of the affection. The chloral was continued for two days, when the occasion for it no longer existed. On discontinuing the drug the patient recovered complete sensation in the part that was anaesthetised.

H. G. an adult male Eurasian, was suffering from an ordinary attack of "ardent" or "sun fever"—an intensified form of febricula, with a tendency to hyperpyrexia; the temperature oscillating between 103° and 105°·5 for several days, and was unable to sleep at night. Urethane, sulphonal, bromidia, and hyoscyanina had been tried in vain; and nothing had the desired effect, till a 25-grain dose of chloral was given. The next day he complained a peculiar numbness of the lower half of the right side of the face, which lasted for about five hours, after waking in the morning. The same occurred the next morning; the dose of chloral hydrate having been repeated during the night previous, and similarly disappeared during the day. It did not recur after the third day's dose. Not one of these cases was affected by loss of motor power over the implicated sensory area, nor was any one of them affected in any way; in all the anaesthesia was localised and temporary.

A PECULIAR CASE OF POISONING.

By Asst. Surgn. B. E. GHARVALA, F.C.S. (Lond.) L.M.S.
First Assistant Chemical Analyser to the Government of Bombay.

A SUBORDINATE JUDGE of Bijapur, a Brahmin by caste, aged about 42 years, was taken ill with fever of about three days' duration. He was reported "as having been fairly well on the afternoon of 18th April. At or about 5 P.M. he received a dose of medicine from a native quack; he soon afterwards complained of burning pain in the stomach, suffered from incessant vomiting and purging, and died about 10 P.M. on the 18th of April." This is the history of the case as supplied to the Chemical Analyser to the Government of Bombay. On analysis arsenic was detected in the viscera. Subsequent to the receipt of the viscera, two solid heavy dark brown masses of the consistence of stone were forwarded. These two masses were called "Hemgarbh Matra" and "Samarpang Matra," and presented the appearance of having been rubbed on some stone or hard substance. On analysis one of them was found to contain mercury and sulphur, and presented some minute particles of glistening material, which was supposed to represent gold, said by the quack to be one of the constituents of the "matra." The other "matra" was found to contain arsenic and sulphur. The medicines which the quack employed consisted of a few grains from both these celebrated compositions—"compounds, the composition of which is kept a profound secret and handed down from father to son, through several generations—a compound which in the present instance was the means of cutting short, a bright, promising and useful career. There is no doubt that the death of the sub-judge was due to the administration of these compounds, for it is admitted that he took ill with all the

symptoms of arsenical poisoning; soon after they had been administered to him, and that arsenic was found in the viscera, and its presence identified in the "matra." I cannot do better than close this article with the warning given by the Chemical Analyser to the Government of Bombay in his last annual report:—

"It is hardly necessary to remark that the possession of one of these "matras" places enormous power in the hands of the owner—a power which can very readily be employed in an unscrupulous manner, and even when used with the best of motives by a skilled person as a *bona fide* medicine, it is practically impossible in a crude preparation of this nature, to form any idea of the quantity of each ingredient present in any given dose, as it must necessarily vary in different parts of the same matra."

A CASE OF PHELGMASIA DOLENS OF THE ARM.

By JOHN MORTON, M.D.,
Mussorie.

A LADY, III para, was confined easily on the 18th instant. Nothing untoward happened till the third day, when the temperature suddenly rose to 104° and excruciating pain was felt in the left shoulder, the inner side of the arm and the flexor aspect of the forearm. Hypodermic injections of morphia were given, but only relieved pain for a couple of hours after their administration. The day after the commencement of the pain, the arm began to swell, and on the third day the whole of the upper limb was characteristically swollen. The temperature kept high for fully a week, and then showed some signs of becoming normal. The uterine discharge during the course of the disease was erratic; for a day it would be profuse and then for another 48 hours it would almost border on stopping entirely. The uterus was kept well disinfected with antiseptics, and all the details of antiseptic midwifery were carried out. The moment therefore of infection must have been when the patient was confined, the labor was very quick and the husband received the child in his hand, before I or the nurse could arrive. The arm has been treated in the orthodox way, by absolute rest, hot fomentations, and anodyne applications. It is almost well now. I think phlegmasia dolens attacking the arm is very rare, and therefore send these notes for publication.

A CASE OF SNAKE-BITE TREATED WITH STRYCHNINE INJECTIONS.

By A. FERMIE, L.R.C.P. & S. Edin.,
Civil Medical Officer, Garo Hills.

GANDRANGE GARO, a strong active man, employed as dak runner, about 25 years of age, was at 7 P.M. on the 15th ultimo bitten on the dorsal aspect of the right foot by a snake some 2½ feet long, of a dark-brown color, beautifully marked with square dark spots. I did not see the snake, but by the aid of diagrams, and the description, I take it to have been a *Trimerurus Monticola*.

The man was brought in to me at 7-45 P.M. There were the marks of two small punctures about one-fourth of an inch apart, from which was oozing a few drops of blood. He had a cloth tied tightly round the leg. His pupils were slightly dilated, the right a little more so than the

left; his pulse was small, thready and rather compressible. He complained of great pain and nausea.

I enlarged the wound and encouraged bleeding, then I injected 10mg. of a 1 gr. strength strychnine tabloid, and in another twenty minutes a second tabloid of like strength. At 8-30 P.M. the man said he was suffering great pain and felt drowsy, when I injected once more, and this time 8m. of the liquor strychninae B. P. About 9-15 P.M. he said he was feeling somewhat better, though he felt some pain and a stinging sensation about the region of the bite and injections. I then washed out the wound with Condy's fluid and kept him in hospital, taking off the ligature round his leg at the same time. The next morning I saw him again when he was able to hobble along with the aid of a stick; though his foot was somewhat swollen. During the two days he remained in hospital he improved greatly, at the end of which time I dismissed him, and in the course of four days more, or six days after the bite, he was able to resume his usual calling, that of dāk runner.

I may state, in conclusion, that the question arises whether the snake was poisonous. The symptoms and prostration of strength seem to point to the existence of poison; though it is possible that this particular snake may not have been so effectual as to kill or destroy a vigorous adult life.

STRYCHNINE IN NICOTINE POISONING.

By AGIA RAM,

Civil Hospital Assistant, Murren.

I was called to see a patient, aged 22 years, who was in a semi-comatose state, presenting the following symptoms:—Sensation completely lost and mind wandering and quite unconscious. On being requested he protruded the tongue. Pulse 105 per minute, temperature between 101°—102°, extremities cold and clammy, body in cold perspiration, respiration quick and difficult; and at times he complained of pain over the right nipple. When I enquired the cause of this calamity, his wife told me that "he had been working three days continuously in a tobacco field, turning the leaves of tobacco &c. Yesterday evening he came home and asked for a smoke. I prepared the smoking pipe and gave it to him. He smoked for about half an hour and then fell ill." I enquired of the wife whether he was in the habit of smoking. Her answer was in the negative, but said he had commenced only two weeks ago. I suspected that the patient was suffering from tobacco poisoning, and I accordingly gave him a mustard bath, some inhalation of spirit ammoniac aromatic, and about 2½ minims of liquor strychnine hypodermically. He regained consciousness in about half an hour after the first dose, every sensation returned, and he was apparently all right, and asked for something to eat. He was given about ½ seer of milk with a little sugar. After two hours he relapsed into his former condition, and again I repeated the strychnine, which relieved him, and the patient was quite well when I last saw him.

The *Englishman* says its North Cachar correspondent reports that in one of the Cachar tea gardens Mr. Haffkine inoculated the majority of the coolies. Cholera visited the garden later and none of the inoculated were stricken with the disease, though many others died.

OUR PICTURE GALLERY.

KENNETH BRUCE STUART, M.D., M.R.C.S. (Eng.)

F.R.C.S. (Edin) F.A.C.S.,

Late Coroner of Calcutta.

THE features of the portrait in our Picture Gallery of to-day must still be fresh in the memory of many of our readers. They are the features of one who in a very marked degree united the characters of trusted medical adviser and beloved personal friend. Even in the long roll of medical worthies who have won name and fame in the City of Palaces few, if any, have achieved a higher place in public esteem or a warmer place in the affections of a very wide circle of friends. KENNETH BRUCE STUART was born in Calcutta on the 12th September 1835. His father, DR. ROBERT STUART, was a well-known and very highly respected physician, who practised in Calcutta for the long period of 32 years. The earlier part of his education he received at the old St. PAUL'S School, in this city, now represented by the school of that name in Darjeeling. With his father's profession in view he was sent to Scotland to complete his preliminary studies in the Medical College, St. ANDREWS. Thence he proceeded to Edinburgh University, in the then famous medical school at which he, at the early age of 21, completed his professional course. Among his college friends may be named DR. W. S. PLAYFAIR, DR. GARROW GRANT and DR. D. B. SMITH. Early in 1857 he was admitted a member of the Royal College of Surgeons, London; and having now made up his mind to compete for an appointment in the Indian Medical Service he, in the autumn of that year, placed himself under the special tuition of DR. JOHN POWER. It is useless to speculate on what might have been if this purpose had been carried out, as it well might have been, to a successful issue; but, unfortunately, the special course had hardly been entered on, when a letter from his father led to an entire change of plan. It was the year of the Mutiny. His father was still comparatively young, but with his long continued service in the trying climate of Bengal, and perhaps under the peculiar strain of the time, his health had given way. He held several important public appointments, and had at the same time an extensive private practice. In these circumstances it was only natural that he should turn to his son for help. With characteristic unselfishness and devotion to duty, KENNETH STUART at once recognised his father's claim to his services, gave up all thought of competing for the Indian Medical Service, and prepared to return to the East. As no examination was available at Edinburgh, where he had studied, he presented himself for examination at St. ANDREWS, and obtained the degree of M.D. on the 23rd December 1857. On his reaching Calcutta early in the following year, his father almost immediately went away for a change, and DR. STUART, though only 22 years of age, found himself put to the very severe test of carrying on his father's extensive practice single-handed. He stood the test and at once established his reputation. This was a very happy beginning of what may be called a partnership between father and son that lasted with unabated confidence and affection till the

lamented death of the former, five and a half years afterwards. In 1841, Dr. STUART received his first personal appointment from Government. He was desirous of returning to Scotland for the purpose of being married. His father's health had greatly improved, and so he could be spared for a few months. Having learned that Government wanted a medical man to take charge of insane soldiers who were about to be sent home *via* the Cape, he applied for, and received the appointment. The voyage proved very long and tedious, and the vessel arrived a month late, to find that she had been given up for lost! But Dr. STUART had the satisfaction of being able to report well on all the patients that had been put under his charge. During his stay in Scotland on this occasion he was elected a Fellow of the Royal College of Surgeons, Edinburgh. He returned to Calcutta before the close of the year and found himself after another year, once more in sole charge of the large practice and of the various appointments held by his father, who from failing health had to go on leave in January 1862, and was never able to resume duty. Dr. STUART was thus called to act as physician to the Mint, the Customs Preventive Service, the Leper Asylum, and the Alms House; and he succeeded to these appointments on his father's death in July 1863 with all the work which they involved and with a practice steadily increasing, his life became a very busy one, all the more so because he was always careful to keep himself abreast of the literature of his profession. He lived for his patients. He never spared himself when it was in his power to serve them, or to advance their interests. This unflinching devotion to duty added greatly to a reputation for skill and resource which steadily rose. At the same time his relations to his brethren in the profession were ever of the most cordial kind. No one was more careful than he in all matters of professional etiquette. He enjoyed the personal regard and esteem of such leading men as Dr. CHEVERS, Dr. CHARLES, Dr. BROUGHAM, Dr. ARCHER and Dr. BAILLIE & Co., who were always ready to help him when in any way he required their aid. The obligation, however, in such matters was not all on one side. Dr. STUART's practice was so extensive that a considerable variety of interesting medical cases came under his care; and more than one of his medical friends saw cases with him which they had never seen before, and used to beg him to let them know when he met with any others. And here it may be interesting to note that some of his prescriptions came to be so well-known that many, who were not his patients, used to go to one of the dispensaries, and without any prescription ask for "Dr. STUART's Mixture," "Dr. STUART's Powder," &c. Indeed the doctor in charge of the dispensary suggested to him that he might add largely to his income by taking out a patent for these popular prescriptions; but such a course was entirely alien to his generous disposition.

With excellent health and thorough enjoyment of his work Dr. STUART continued at his post without a break until March 1871, when he took six months' leave to enable him to accompany his family to England. So thoroughly had he established his position in Calcutta that some of the very first men in the profession gladly lent a hand

in carrying on his practice during his absence. And so it was, on all subsequent occasions. To the last he could reckon among his personal friends such men as, to name only a few, Dr. D. B. SMITH, Dr. COATES, Dr. ELLIOTT, Dr. MCCANNELL and Dr. HARVEY. Of his career after his return to duty in 1871, no more need be said than that it continued to be marked by the same quiet enthusiasm, the same conscientious devotion to duty, the same self-sacrificing regard for others on his part, and on the part of his patients the same affectionate esteem and confidence. It should however, be noted, though he himself, as one who did good by stealth, would have been the last to permit this, that he added very largely to an already heavy burden by the extent to which he rendered gratuitous services. It has ever been the glory of the medical profession to give its services without fee or reward when such a course seems necessary; and with patients so numerous as his, exposed to all the changes and chances of life in a city like Calcutta, Dr. STUART had his own share of such cases and never failed to respond. The tale of his innumerable deeds of kindness to the broken down, the forlorn, the outcast, the poor, whatever their creed or nationality, cannot be told here. But he had also carried with him to Calcutta the very generous practice that used to prevail among medical men in Scotland, who declined to accept any fee for services rendered to those in the clerical profession. Accordingly, he numbered among those to whom he freely gave his services many ministers and missionaries connected with the various religious denominations in the city, together with their families. And most ungrudgingly did he serve them; in not a few cases he had the patients brought to his own house, so that he might the more effectually attend to them. There are those alive to-day who can never forget that, humanly speaking, they owe their lives to Dr. K. B. STUART, and who lovingly cherish the memory of the unceasing care and tenderness and resource by which he rescued them from the very jaws of death. It was one such, a missionary's wife, who worked for him the text he loved to think of as a motto: "I was sick and ye visited Me.....Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto Me." But Dr. STUART must not be regarded as caring only for things of his own profession and practice. His was a broad, genial, sympathetic nature. He took a large-hearted and large-minded view of his duty as a member of the community. We find him having an important part in a great variety of institutions, educational, philanthropic, charitable, and religious. His services to the Leper Asylum, the Alms House and the Fendall Home may be recalled. He was a warm supporter of the Doveton College, and willingly lent his aid for many years in the management of that institution. He took a very prominent part in carrying on the work of the Uncovenanted Service Family Pension Fund, which has proved such a boon to many a widow and orphan. And so convinced was he of the utility of such institutions, that he was one of the first and warmest supporters of the General Family Pension Fund.

It was in 1876 that he first discovered the presence of organic disease in his system. He continued two years longer at his post, as the disease was not severe in form,

Yours sincerely
Kenneth B. Stuart

and his medical adviser, Dr. CHARLES, was of opinion that he would enjoy as good health in India as in England. During a six months' leave in 1878 he took the opportunity of consulting Dr. PAVY in London, who entirely confirmed the diagnosis that had been made two years previously in Calcutta. Returning to the East, he resumed work with his usual cheerfulness and assiduity, and even added to his burden by giving a larger share than ever of his time to those demands which come in ever-increasing volume on men who have won public esteem and confidence. The disease that had seized on him advanced slowly but steadily. He knew it could have but one issue; it was the messenger of death; but he worked on with a brave, unflinching heart. If there was any difference it was only that he gave himself, if possible, more faithfully and diligently than ever to the discharge of duty. No one who saw him on his daily round, or at some public board, or in his hospitable home in Kyd Street could ever have suspected that he was consciously living under the shadow of death; he was still so bright and cheery and active. His last visit to England was paid in 1881. This was his longest rest, for he did not return to duty for a whole year. The rest was very welcome, and he enjoyed it greatly, but he longed to get back to his work. It had always been so when he was on leave, for his patients were to him personal friends, and he was ever wondering how they were getting on. And he had the gratification of knowing that this warm personal interest was cordially reciprocated. Many were the tokens of individual affection and gratitude that he received from time to time; and in 1879 on the occasion of Mrs. STUART's return from England, his patients united in presenting her with a substantial token of their deep regard for herself and her honored husband.

In March 1884 Dr. STUART was made a Fellow of the University of Calcutta, and took his place in the Faculty of Medicine. The following month brought him his crowning honor, his appointment as Coroner of Calcutta. His appointment was hailed with special satisfaction. He had an unrivalled acquaintance with Calcutta; for he had been longer in practice than any other medical man in the city; and he had taken a position in the esteem and confidence of the public "certainly not inferior to that of any of his brethren in the services." The new duties were a very heavy addition to his burden, but the work was entirely to his mind, and he gave himself to it with such vigour and energy that he speedily mastered the details, and surprised even his friends by the ability and skill with which he discharged the duties. The late Dr. COUL MACKENZIE, who as Police Surgeon came much in contact with him as Coroner, was greatly struck by the remarkable success of his work. "You were doing admirably," he said to Dr. STUART after his health had given way. "You were doing admirably; but you ran, when you should have walked." It was Dr. STUART's way. He spared no pains in matters of work and duty; he must always do his very best; whatever his hand found to do he did with all his might. The heavy strain speedily began to tell; all the more that, some months before, a serious development of organic mischief had taken place. As early as May he was urged by his medical advisers to go away for a change, but in view of his recent appointment he was anxious to defer doing so till September, the month he always dreaded most of all the year. His strength was more nearly exhausted than any one suspected, and on the 24th June he completely broke down. A change to Coonoor gave for a time some promise of a rally. It was a lovely spot, and he greatly enjoyed the rest. Indeed he was able to take pretty long walks, and even his old brightness, which for a little had forsaken him, returned. The improvement was only temporary. Early in October he began to fall back, and it was resolved he should return to Calcutta. His indomitable spirit once more asserted itself, and he actually resumed work for the first half of November, only however to find that the effort was greater than he could

sustain. He might have left Calcutta for Coonoor, as some of his medical friends advised, but he knew that no change could now restore his health, and he desired to die where he had so long worked. Within a month the end came; he passed away on the 14th December 1884, at the early age of 49. Tributes to his memory appeared in the leading Calcutta papers, and memorial minutes were adopted by the various bodies on which he served; but perhaps the most touching proof of the profound regret called forth by his death was supplied by the numbers of his patients and friends who for months after continued to visit his grave in the Park Street cemetery. Such spontaneity of universal sorrow was at once a surprise and a comfort to his bereaved family.

Dr. STUART's memorial as a medical man is to be found not alone in the distinction he achieved, or the honors he won, but rather in the grateful and loving remembrance of him by his numerous patients as the true type of a trusted family physician. He had a keenly sensitive nature, but his sensitiveness was so blended with sympathy and unselfishness, that it only added a grace to his natural charm of manner. A warmer heart never beat in human breast; never was there a truer, nobler character. He had a remarkable power of winning affection and attaching friends. In the sick room he was sympathy itself; his bright sunny presence was an inspiration. He won for himself a special reputation for the successful treatment of children. He had the happy knack of winning the confidence of the little folks; indeed he used to lay himself out for this, and his patients will readily recall some of the ways in which he set to work. "I always make friends with the children," he would say, "when they are quite well, and so when they get ill, they are not a bit afraid of the doctor, and shew their tongues quite readily." He had a wonderful faith in the vitality of children which made him refuse to give up hope of their recovery till the very last. Ever most tender and assiduous in his attention to the little sufferers, his resource seemed all but boundless; and he had the supreme satisfaction of recording complete recovery in some of the most desperate cases. Indeed it was much the same with old and young. Patients of his to-day remember with profoundest thankfulness how he tended them, or pulled some loved one through when hope was gone.

Dr. STUART, was in the fullest sense of the term, an honorable man with a remarkably high sense of duty and a deeply sympathetic nature, but the master-key to his character and work was his profound faith in God. An essentially religious man, his religion was not of the obtrusive or effusive kind, but still, deep, all-pervading; in a word he was ever a Christian gentleman. His profession gave ample verge and scope for his sense of fears in mortal things, and his own long illness might well have caused perplexity, but his faith in Divine Love and Guidance never faltered. And so he could face death with a brave heart and a calm assurance that all was for the best. He ever lived "as in the great Taskmaster's eye." Of himself or any service he had rendered to any one he thought very little; his ambition was simply to do good; he was content, with Sir HENRY LAWRENCE, to have "tried to do his duty."

The happy and hospitable home so well known to Dr. STUART's friends has long been broken up. Mrs. STUART and her two daughters now reside in London. The elder of two sons has adopted the medical profession and now carries on a large practice in the University City of Durham, following close in his father's footsteps. The younger son is winning golden opinions as a civilian in the North-West Provinces, and will, doubtless, be heard of by and by in some of the higher posts of the service.

Miss Dora Caine, M.B., daughter of Mr. W. S. Caine, M.P., has been appointed House Surgeon to the Children's Hospital at Hull.

THE Indian Medical Record.

1st July, 1895.

SOME CONSIDERATIONS ON THE USE OF ALCOHOLIC STIMULANTS.

WHEN in 1893 the feeling ran high that there was a pressing necessity for more stringent legislation than that existing for dealing with habitual drunkards, there was probably a fear that the drink curse was considerably on the increase; and the unanimous opinion of important and influential medical and surgical men and bodies, tendered before the Departmental Committee on inebriates, of the need for the compulsory exclusion of inebriates, suggested rather a gloomy, if not a hopeless, picture in the matter of alcoholic consumption. We have to thank God however, that the British nation is not quite so bad in this respect as it has been feared; and that it has not been drifting alarmingly into alcoholic abuse. A record of the nation's consumption of alcohol, tea, coffee, cocoa, tobacco, and chicory for the thirty-two years, 1861—1893 shows that while in 1861 the consumption of wines and spirits averaged 1.22 gallons per head of the population, it averaged 1.35 gallons in 1893. This cannot be regarded as an alarming increase; but alongside with this, there is the more pleasant consideration that the use of wines and spirits has fallen steadily since 1876, when the average consumption reached its highest (1.80 per gallon per head of population) in the period 1861—93. The increase in the consumption of beer however, has been rather large, having stood at 24.3 gallons a head in 1861, and at 29.6 gallons in 1893; and if the conclusions of Dr. J. MURRAY GIBBS in an article contributed to *Hygiene*, viz., that the drink of a nation tends to the formation of the national character, and that beer creates a selfish, argumentative, quarrelsome disposition, be correct, England's belligerent proclivities must have been considerably stimulated in recent years; and this may afford a physiological explanation of our many brawls and political complications with frontier and other tribes! With regard however, to the free use of beer, we have the opinion of Dr. OTT of Philadelphia, who has had fifteen years of experience among beer-drinkers—that a free indulgence in malt liquors results in a ruddy countenance and a cheerful laughing disposition; and with these diametrically opposite opinions of the two doctors we are at a loss to decide whether the increasing beer-drinking proclivity of England is an omen for good or evil.

In the record under consideration, we are told that the consumption of tea, coffee, &c., has increased from 4.38 pounds per head of population in 1861 to 6.90 pounds in 1893. Now whatever be the stimulant or beverage adopted as a national drink, or generally used by a nation, it is admitted that its abuse is a source of harm. Dr. J. MURRAY GIBBS in the article already referred to, says that their and caffeine act on the intellectual system and on the nerves controlling digestion, and that a continuous or prolonged excitation of these by an irrational use of tea, coffee, &c., results in indigestion, and that excessive

use of these non-alcoholic beverages has much to do with filling our lunatic asylums. In connection with the foregoing it is interesting to consider the remarks of Dr. PETERS, before the Toronto Medical Society, &c., that notwithstanding the progress and improvements that have been made in many an important direction in our profession, within the past thirty years, we are yet confronted with the regrettable fact that nervous and mental diseases have increased largely. Many or several causes may, of course, contribute to a result; and the increase in mental and nervous disorders of the past thirty years can be explained in various ways; but it must not be forgotten that the excessive use of tea, coffee, &c., is one of these, and that while we counsel temperance in alcoholic drinks and the substitution for them of non-alcoholic beverages, we must not regard the latter as wholly harmless, or that they may be indulged in to any extent with impunity. We have no doubt but that the temperance movement of recent years has given much impetus to the tea trade, while the extension of education and of religious influences and teachings have helped materially in the dangers from alcoholic abuse being better recognised and more feared. While physical evils doubtless result from the excessive use of non-alcoholic stimulants, those evils are not so readily induced or of so permanent a nature as the evils following unreasonable alcoholic indulgence; and viewed in this light, the record of the use of stimulants for the past thirty and odd years is certainly not alarming, if it even cannot be pronounced satisfactory. And if all those who push forward the consumption of the their and caffeine containing beverages, will but bear in mind the evils of the excessive use of these, and if in their advocacy of their adoption in substitution of alcoholic drinks they combine mild counsel against carrying the thing too far, we may, in regard to the use of stimulants, expect the nation's record of the next thirty years to be even more satisfactory than that of the past.

It would indeed be very interesting to have similar statistics as to the consumption of stimulants in India. In the matter of the use of alcoholic stimulants by the people of India, we have had some facts and figures given to us in a lecture delivered in the Baring Institute, Mussoorie, on the 29th August 1890, by the Revd. THOMAS EVANS. The figures and statements, however, do not permit of things being worked out to arithmetical conclusions, but allow only of unsatisfactory inferences being drawn. Mr. EVANS shows that the people of India were not always the abstemious and drink-hating people they are supposed by many to have been; but from the Vedic age to about the sixth century of the Christian era the drink tendency steadily increased, until it grew to be regarded and denounced by leaders of the age as a positive curse. The practice received a great check during the occupation of the country by the non-drinking Mahomedans. Mr. EVANS is, however, of the opinion that the people of the country have grown fearfully drink-loving in more recent times; and these are his sad conclusions:—"The drink traffic of late years has advanced with grant strides in India, and I am sorry to add that the evil continues to grow more and more. Having now for two years travelled India from north to south and mingled with all classes of the people, whose habits and

languages I know, I have found that indulgence in strong drinks has already spread more or less among all classes and creeds in the country, in spite of the strong denunciations of the Shastras of the Hindus, and the Koran of the Mahomedans."

We think that this is the general opinion and the prevailing belief as to the spread of drink in the country. MR. EVANS' statistics are however, not sufficiently satisfactory. His conclusions are drawn from the following figures:—

The excise revenue of the Madras Presidency rose from 21 lakhs in 1850, to 97 in 1888. In the Bombay Presidency the general average of receipts for the five years ending 1882 was exceeded by 37 lakhs in 1889.

In 1888 in Bengal there was an increase of 48 lakhs of rupees over the annual average of a long period previously. About 1890, the excise revenue for the whole of British India was 500 lakhs; while twelve years previously, it was but 230 lakhs. If these figures were worked out, as in the case of the British record, into the number of gallons of spirits which they represent as consumed, and the average consumption given per head of population in the years and periods under reference, one could form a more satisfactory idea of the increasing demand in this country for alcoholic stimulants. The figures given by MR. EVANS shew that the excise revenue has more than doubled itself in recent years, and as our population has by no means increased to this alarming extent and the amount of duty per gallon has not been raised, there is good reason for believing that the country is being fast and fearfully swayed by the subtle influence of alcohol. It is a great sign of the times that a Hindu, though he have little or no thought or desire of embracing Christianity or relinquishing his faith for any other, is very much less than of old, a respecter of those social and religious rulings which stand in the way of his being English-like, and he is willing to spurn the warnings of the Shastras against the use of alcohol, so long as he believes that its use is little less than an English social necessity. We hope, however, that seeing that England's consumption of ardent spirits has declined since 1876, they would follow suit and help to reduce the expenditure of alcohol in India. In considering MR. EVANS' calculations, it must further be borne in mind that in a country like India, it is impossible to say to what extent the people of India themselves have shared in this increased consumption of alcohol, and how far the European population have caused that increase. Our European and English-speaking population has been growing, and this will to a great extent explain the increasing demand for spirituous liquors. At all events all the blame cannot be charged to the people of India. And as it will ever remain little short of an impossibility to determine how much of the spirituous drinks used in the country have been consumed by its people and how much by its British occupants, we can scarcely hope to be ever able to gauge the true fall or rise in the drinking habits of India's people.

A careful analysis of the London *folo de se* statistics from 1884 to 1884 convinces DR. OGLE that June is the *suicide season* as it shows 1,022 per 10,000 suicides, while 697, the lowest figure, falls to December.

THE PARLIAMENTARY COMMISSION OF ENQUIRY INTO INDIAN EXPENDITURE.

THE decision of the British Parliament to appoint a Commission to enquire into the vast expenditure that is involved in the British administration of the Indian Empire, is a supreme opportunity for India's good, if only fairness and straightforwardness are exercised by the Indian Government in permitting such Commission to receive evidence from independent witnesses, qualified to speak on subjects of which they have the fullest cognisance, even though the knowledge and experience thus placed in evidence before the Commissioners should tend to expose a system of mal-administration and extravagance which condemns the past policy of the Indian and Provincial Governments. If, we say, the authorities in India are prepared to approach this Commission of enquiry into Indian affairs in this impartial, fearless and frank spirit, then there is a hope that India's highest good will be acquired by their deliberations; but if all outspoken truthful testimony, condemnatory of the past and present doings of the Government, is to be hoodwinked, pigeon-holed and smothered, so that the voice of the burdened and oppressed is rendered inaudible and impotent, then, of course, corruption and injustice and flagrant extravagance will reign unmolested, and the Commission will be a huge official farce. It is too well known and too keenly felt in India that the official bureaucracy can do anything and everything alongside of the well-adjusted machinery of Indian officialism; while independent non-officialism is nowhere. Government can do as it pleases, since the voice of the people does not and cannot affect its policy. There is no public opinion worth the name in India, to guide or coerce the Government in its actions. Most of the so-called independent journals are subsidised by the Government, and they are prepared to be dumb at the bidding of high officials. Hence it is that the people of India naturally dread the outcome of "Commissions," since such Commissions are made and ruled by the Government. However, let us hope that matters are not going to be so bad this time. Let us approach the Indian Government on the present occasion with the trustful hope that our voice and prayer will have a hearing, and that in matters medical, the authorities will allow the local medical profession to place its evidence before the Commission. We say the opportunity is a supreme one; it is unique in the history of Indian administration, and should inspire in us new hope, new energy, and fire us with enthusiasm and zeal in the great cause of advancing the claims of the local profession to a fair and equal share in every avenue of State work in the Indian Empire, so that every medical man in India may feel and know of a truth that the ladder which leads to honor and distinction in his profession is free and open to him, from the lowest rung to the highest.

Then there is the important question of expenditure on the medical services of this country. We have shewn by a careful system of mathematical calculations that the State Medical Services of India can be remodelled without endangering their fullest efficiency, and that in so doing a vast saving can be effected, amounting to several lakhs of rupees per annum. We have shewn that the separation of the military from the civil medical services will lead

to substantial economy, and we have proved that the inauguration and establishment of a purely civil medical service for the needs of the civil population, not only abolishes an extravagant, unpopular and unjust anomaly, —namely that of employing *military* surgeons in civil work at double charges—but brings into effect a perfect and stable machinery for civil work. We have shown that a great reduction of the Army Medical Staff with British troops can be easily and efficiently brought about by the larger utilisation of Military Assistant Surgeons and this upon the substantial evidence that Army Surgeons have little or no work to do. We have also explained how in our large cities the work of our large hospitals might with real advantage to the public and to the State, both from an educational and an economic point of view, be carried on by honorary staffs, thus abolishing the present expensive and often ineffectual system of utilising *military* surgeons for this purely civil line of work.

It is in the larger use of locally trained medical talent European, Eurasian and Indian, that real economy can be effected.

We shall not enlarge upon these topics, we simply throw them out as head-lines to be used for further consideration and discussion, and we would strongly urge upon the Indian Medical Association and the Medical Association of India to join hands and request without delay that the Government of India will graciously permit the evidence of this united body to be placed before the Parliamentary Commission now appointed to enquire into the expenditure of India.

In this movement there can be no question of personalities or individual claims. It is too general and corporate, and effects the well-being and future of the medical profession of India as a whole. Let us then display a united front, Bengal and Bombay and Madras, one amalgamated phalanx. Of course it can be done, and if all agree it *will* be done. So mote it be.

COMMENTS AND NEWS.

FEEDING AFTER WEANING.

IN feeding infants about to leave the mother's breast, thinks DR. W. L. STOWELL, we must fix the principles and prescribe with common sense according to the case in hand, as on the mode of weaning hangs the *whole* of the subsequent life of the little one. We know that perfect nutrition demands waste and removal of tissue, as well as new aliment composed of nitrogenous and fatty matters, carbohydrates and salts of lime, &c., in which however, the carbon absorbed by children requires to be three or four times per pound weight as that needed by adults, but as the exact weight or exact age of the child is not a proper criterion in arranging a dietary, due regard must be paid for season and individual idiosyncrasy. Except in cases of acute illness of the mother, the child should be *gradually* weaned as soon as the teeth begin to come, i.e., between the 8th and 8th month, when diluted cow's milk will be the most appropriate food; but after two or three months it may be supplemented by easily digestible starches, and as the ptyalin develops, meat and other nitrogenous compounds are indicated. Bulky food stimulates digestion, but concentrated foods are to be avoided as not promoting natural activity; and fried food, re-cooked meat, and rich foods are interdicted as the little one's system is not

strong enough to wrestle with foreign substances in excess of natural diet. It being remembered that in the *excess* of one ingredient begins the mal-assimilation that ends in indigestion; sugar and starch in moderation are good as they assist exudation, but in large quantity they detract from what should go to the albuminoids, and often set up persistent gastric irritation.

Table of food Values.

| | Hours for digestion. | Carbo Hydrates. | | | | | | Total Salts. |
|--------------------|----------------------|-----------------|-----------------|--------|---------|--------|--------|--------------|
| | | Proteids. | Carbon and Fat. | Sugar. | Starch. | Salts. | Water. | |
| Human Milk | 2-00 | 1-78 | 3-88 | 0-84 | .. | 0-38 | 87-22 | 12-66 |
| Cow's Milk | 3-00 | 2-75 | 3-75 | 4-42 | .. | 0-68 | 87-20 | 12-61 |
| Eggs { Raw | 1-50 | 14-00 | 10-50 | .. | .. | 1-50 | 79-00 | 20-00 |
| { Boiled | 3-00 | | | | | | | |
| { Hard boiled | 3-15 | | | | | | | |
| Bread { Stale | 2-00 | 8-10 | 1-00 | .. | 51-00 | 3-30 | 57-00 | 62-00 |
| { Hot | 2-15 | | | | | | | |
| Potatoes { Baked | 2-20 | 2-10 | 0-20 | 3-20 | 18-50 | 0-70 | 78-00 | 22-00 |
| { Boiled | 2-30 | | | | | | | |
| Beef Cooked { Lean | 3-00 | 19-50 | 5-50 | .. | .. | 5-10 | 72-00 | 28-00 |
| { Fat | 3-00 | | | | | | | |
| Fowl | 4-00 | 21-00 | 5-50 | .. | .. | 1-70 | 74-00 | 26-00 |
| White fish | 2-00 | 18-10 | 3-90 | .. | .. | 1-00 | 78-60 | 22-00 |
| Apples | 0-22 | P-2-72 | 7-88 | .. | .. | 0-44 | 86-04 | .. |
| Bananas | 0-42 | F-0-53 | 19-65 | .. | .. | 0-78 | 73-80 | .. |

The millionaire's pet and the labourer's child start with the same anatomy, but while the former has every want supplied, the latter must take what it can get. From the above table, we note that meat contains the most salts and the most nitrogen, and ROUTH says, "children need much meat to build up their bone and muscle, but as prolonged cooking coagulates the albumen of the meat and only extracts the salts, beef tea, to be of any value, should be a cold infusion of a pound of steak to a pint of water, not heated until just before serving." Fruit is admissible after the second year, but stimulants *never*, and at the sixth or seventh year when the deciduous teeth fall, the child must be urged to chew his food thoroughly and eat slowly; while at the approach of and during puberty *rich* foods or highly spiced viands should be strictly avoided, lest they increase sexual excitement in the immature.

THE PHYSICIAN'S RELATION TO THE LAITY AS REGARDS THE HYGIENE AND PHYSIOLOGY OF THE SEXUAL ORGANS.

TRUE physiology teaches that in the *proper* exercise of any natural faculty or propensity in man, there is *nothing* that is impure, unholy, low, sensualizing or in any way degrading but, as DR. S. B. ELLIOTT points out, though every second of the hour a human soul is born into the world, the majority, by far, of these swell the gruesome list of unfortunates, whether of the imperfect, the vicious or the diseased, simply because too little discretion is exercised in the matrimonial state in which people mate with every one and any one, regardless of health, age, temperament, and the means or ability to support and educate a family; while an abominable mock-moesty and hypocrisy urges the law, the clergy, the medical profession and intelligent parents to keep the masses and their children in ignorance of the function of reproduction being the most influential of all others on the morals, physical status, public health, population, disease, mortality, personal reputation, property, legitimacy and even life itself, of human beings. *Thousands* of women suffer from uterine diseases and disorders and lack of vein, tonicity and vigor, as the result of either too little attention paid to prenatal influences or of too frequent and improper sexual intercourse, neither of which would occur were the masses not sinfully kept in ignorance that stimulants, over-rich food, ill-assorted marriages, sexual excesses and lascivious talk, all conduce to develop permanent congestion and constant irritation of the pelvic organs predisposing to precocious and entirely morbid amateness resulting in vice, misery and

disease not in themselves alone, but in their innocent offspring also. Bad habits must be corrected from the cradle, where habits are too often encouraged to play with their genitals, and children must be taught to eat, drink, dress and exercise hygienically and must be given proper moral instruction; for it is the greatest fallacy to attempt to separate the mind and body in educational arrangements when nature teaches the inseparable relation of the moral and the physical life. Here then lies the solemn duty of the physician to rend asunder the veil of mock-modesty by insisting on parents teaching their children the true hygiene and physiology of the sexual organs, instead of letting them be initiated into this subject by carnal practices at the instigation of persons of low morals; and these lessons of abstinence and continence should be firmly and irrevocably inculcated before puberty, when the sudden and rapid development of the sexual organs, with their consequent great amorous impulse, instinctively point to touching and manipulation with every risk of either too early yielding to carnal temptation or of contracting the baneful habit of masturbation which may mean the ruination of the victim morally, mentally and physically; and Doctor! lay the lesson well to heart that you are criminally guilty and a moral coward if you do not enlighten your patients of the importance of regulating pre-natal influence and nipping bad habits in the bud.

SOME FACTS ABOUT THE RECENT SMALL-POX EPIDEMIC IN CALCUTTA.

DURING the quarter ended 30th March last, there were 1,235 deaths from small-pox within the Municipal limits of Calcutta, a greater number than in any quarter since 1865, when there were 3,001 deaths during the same period. Of the cases reported, 1,022 occurred in Urban Calcutta as against 64, the mean of the previous decade, and 213 in Suburban Calcutta as against 25, the average of the preceding five years. There were 139 deaths in January, 320 in February, and 770 in March. Of the 1,235 deaths, 735 were males and 504 females; 756 occurred among Hindus, 358 among Mohammedans, 110 among Christians and 11 among other classes. The mortality fell heavily on infants under five years of age, no fewer than 384 or 31.1 per cent. of the total number of deaths being under that age, and of this number 279 were under two years of age. The mortality between five and ten years of age was small, being 48; between 10 and 20 years of age it was 113, between 20 and 30 it reached 302; between 30 and 40 it amounted to 242; between 40 and 50 it was 98, and above 50 years of age it was 48. As many as 851 of the 1,235 deaths or 68.9 per cent. occurred in huts, and the remaining 284 or 31.1 per cent. in brick houses, shewing that the mortality was greater among the poorer classes. Colootollah and Mochheepara Wards, which are inhabited by a low and migratory class of the population, furnished 376 deaths or 30.4 per cent. of the total in the town, while Hastings had no death from small-pox during the quarter. Of the 1,235 deaths, 248 or 19.7 per cent. were reported to have been vaccinated, 247 or 20.0 per cent. to have been inoculated and 686 or 55.5 per cent. to have been never vaccinated or inoculated. There were 58, or 4.7 per cent., whose condition was unknown, and there was one who had previously suffered from small-pox. There can be little doubt that many of the 248 deaths reported as previously vaccinated do not really belong to this group. Some of the statements of friends of the deceased as regards vaccination were afterwards ascertained to be incorrect, but in the majority of cases, it was impossible to ascertain the real condition of matters. Inoculations were also not uncommonly mistaken at first for vaccination.

According to a return just issued, 28,140 males and 13,244 females were vaccinated in Calcutta during the months

of January, February and March last. The fees realised for private vaccination during that period amounted Rs. 3,440-4-0 against Rs. 354-4-0 during the same period the previous year.

PHYSIOLOGY AND SURGERY OF THE SPLEEN.

Cor sentit, pulmo loquitur, sed contactu trax, splen ridore facit, cogit amore jecur, or, while the heart felt, the lungs spoke, and the bile contained anger, the liver was the seat of love and the spleen was made for laughter, so thought the ancients; but while in later times to be splenic was to be bad tempered, modern research shews that the functions of the spleen have nothing in common with emotional states, yet nobody knows for certain what part the spleen actually plays in the animal economy, as the survival and thriving of animals after the extirpation of this gland point to the conclusion that of all the large organs the spleen is the least necessary to human existence. While GIESKE confirms DUPUYTREN'S observation that accessory spleen is common in young persons, and especially in foetuses, ROSENMULLER came across only 6 instances in 480 cadavers. J. P. WARLESSE agrees with VULPIUS' decree that except in leukemia, chronic congestion and amyloid degeneration, the spleen is quite susceptible of legitimate surgical attack. VULPIUS furthermore shews (1) the possibility but not the certainty of the entrance of colorless cells in the circulation from the spleen, which disintegrates the red cells, but does not necessarily form or reform them. (2) No positive difference in the blood of the splenic artery and of the vein. (3) Enlargement and increased activity of the spleen in acute general anemia, and while the spleen is thus congested, the blood is found to contain the maximum of red cells and the minimum of white. (4) The thyroid gland has no vicarious relation to the spleen. (5) Removal of the spleen causes only a transient decrease in the red corpuscles and increase in the number of white cells. (6) After total removal of the human spleen there is no splenic development, but there may be vicarious hypertrophy of an accessory spleen, within the ligamentum gastrosplenicale, of a roundish form and varying size, but without a hilus. (7) In persons without spleen the regeneration of blood is retarded after hemorrhage. (8) After extirpation of the spleen the lymph nodules and the bone-marrow acquire an increased blood-forming activity.

ABUSE OF MEDICAL CHARITY.

WARNING notes are being sounded from the West that many of those who can well afford to pay for medicine and medical attendance deliberately take a mean advantage of gratuitous consultations and treatment even to cruelly depriving the really poor and truly deserving of hospital room and necessary medical attendance. That such a thing should be allowed to exist is a crying shame and an abominable holocaust of sacred charity, but as DR. G. F. SHEDDY sensibly points out that these pincies and malpractices will continue so long as dispensary doctors and beginners of the Galenic system gratuitously treat every patient who comes in the hope that they may extend their out-door practice or *limn* some one who can afford to pay a trifle. That by doing this there is not the least doubt that times without number "charity" is extended to those who have no right to expect or demand any, and this wholesale "giving away" of medical favors to those who are well able to pay for them is not only robbing the poor, but also "cutting our own throats." In the rush of business and the multiplicity of calls on his attention it would be impossible for the physician to discriminate between the rich and middle or poorer classes or the deserving from the mass of undeserving, and to prevent this imposing on the charitable instincts of the profession it is urged that only three methods are practicable: (1) Refuse free medical aid to any one not presenting a certificate of

poverty from any charity-organization society. (2) Refuse to act as unpaid or honorary physician to any charitable dispensary or hospital where free advice is given. (3) Maintain the dignity of the profession and so unite together, that when one of the profession is insulted by hospital managers or dispensary trustees, there will not be a crowd of eager brethren in line for vacant places.

EXPERIMENTS WITH TOXIC PRODUCTS ON MALIGNANT GROWTHS.

THE *Journal of the American Medical Association*, summarizing the experiments of DR. W. B. COLEY of New York City with toxic products on malignant growths, finds that of forty-four cases the results have been satisfactory. The cases were made up of sarcoma, carcinoma, and of doubtful sarcoma or carcinoma. The doubtful cases are put out of consideration, as also are the cases of carcinoma, as the results of the treatment with regard to them were not conclusive, and twenty more cases of sarcoma alone are analysed as follows:—One case of recurrent sarcoma of neck and tonsil, which was twice operated on, and of which no hope was entertained, after three years of cessation of toxine treatment, had but a trace of tumor left and no tendency to the recurrence of malignancy. An equally hopeless case continued well fourteen months after treatment was stopped. One case was well twelve months and another three months after treatment was discontinued. One case was well after one year's treatment; eleven cases showed marked improvement, and ten slight temporary improvement under the treatment. In three no effect was produced. In his earlier cases DR. COLEY tried to effect a cure by producing erysipelas by direct inoculation, but found the procedure uncertain and even dangerous. He concluded that the active principle was the toxic product of erysipelas, and hence adopts the treatment of injecting the toxic products.

THE REGISTRATION OF MIDWIVES.

A BILL is now before the House of Commons for the compulsory registration of midwives and the prevention of accouchements by unqualified persons. This Bill provides that midwives should be altogether independent of medical men, and that they may only attend cases of "natural labor;" but unfortunately no provision is made for protecting the public from dangerous ignorance or for penalties or for the punishment of unregistered persons who may continue to practice midwifery *ad lib* and flourish unchecked, while other clauses in the "draft" are so foolish and so detrimental to the interests of the medical profession that a London contemporary writes that the most careful attention of medical men must be given to this matter, and united action taken in strong opposition to it if they desire to avert the grave dangers to themselves, to their profession and to the public, and prevent the wholesale slaughter of innocent babes and parturient women, which would result inevitably, if the Bill for the Registration of midwives becomes law in its present highly unsafe and ill-advised propositions and enactments.

CHARITY ORGANIZATION AND MEDICINE.

As slowly but aye too surely, the old style of hospitals, dispensaries, &c., originally started for advertising individual powers and so securing a large share of practice and since then regularly maintained, is sapping the life blood of the medical profession, by taking away patients, who could pay, from adjacent physicians, DR. GEORGE M. GOULD notes that these evils and others closely allied to them instead of being endured, ought to be cured by getting into personal relations with our dependents to procure a permanent cure by thorough means, of the causes which led to the sickness instead of perpetuating unhealthy conditions and increasing

sickness and disease by "bits" of ineffective treatment; but the prevention of disease in the future can only be obtained by every doctor and every intelligent citizen co-operating to secure individual health and vitality by hunting out diseased sick persons, looking after them till complete recovery, and in these ways cure disease and the allied evils by which the universe is cursed with paupers, blind, deaf, dumb, idiotic, imbecile, insane and all others of the class for which charity is solicited.

TIGHT LACING.

A GREAT deal of controversy is running on this question. Some argue that tight lacing conduces to the begetting of a degenerated weakly progeny and obliteration of the roots of the dorsal nerves in at least 80 per cent. of the corset habitues, and others contending that wasp-waists are quite compatible with health and elegance of form, but the majority of observers agree that though tight lacing does produce bad results, still these results to a great extent depend on the amount of constriction employed, and since the richer classes have abandoned "five ladyism" for golf, tennis and other healthful exercises, corset wearing has not prevented present-day English women from growing taller and finer than ever, even though their mothers were addicted to tight lacing, nor have the male youth of Great Britain suffered for their mother's variety. Yet it is an admitted fact that the woman of the poor are bigger and healthier than their mothers, and give birth to stronger and better developed offspring.

SUCCESSFUL AND DESERVING HOSPITAL ASSISTANTS.

THERE are among the Hospital Assistant class a large number of really able and deserving young men, who simply lack opportunity and encouragement to give abundant evidence of their exceptional fitness for posts of trust and professional promotion. In Madras, the death of one of the collegiate staff, who was at one time a Hospital Assistant, brought into prominence the excellent tutorial work done for many years by this gentleman, and it was thought that his mantle would have fallen on a member of his own class, but it seems things have arranged differently. Among the many applicants for the post was Hospital Assistant C. A. THORNMAN. This young man is a matriculate of the Madras University, and at the examinations stood first in almost every subject in the curriculum in a batch of 80 students. His past collegiate career has been remarkable for its usefulness and success, and the eulogiums passed on his conduct and work by surgeons of the Indian Medical Service, under whom he has served, are exceptionally good. There are others in his service as deserving as MR. THORNMAN, and we sincerely trust that the Surgeon-General of Madras will not lose sight of the merits of these humble subordinates, and that encouragement may be given them.

SAMUEL WELLS, M.D.; LONDON.

IN the death of DR. SAMUEL WELLS of Madras, the Eurasian community has lost one of its brightest ornaments. He was educated entirely in Madras, and was the Johnstone Gold Medallist of his year. He proceeded to England, and after a brief residence obtained the much-honoured degree of M. D. of the London University. For twenty-five years he held medical charge of the Hosur Remount Depot, and was held in high esteem by the Madras Government for his faithful services and his many sterling qualities. DR. WELLS was a patriot of a high order, second only to his renowned friend and colleague D. S. WHITE, the ABRAHAM LINCOLN of Madras. He was highly respected and loved by the domiciled European and Eurasian community, and was Vice-President of their Association. DR. WELLS died on the 4th June from Bright's disease. He lived a quiet life, and was known not so

much by any stirring episodes, but by the elevating and inspiring influence of his course of pure living and good works.

A WOLF IN SHEEP'S CLOTHING.

AN anonymous scribbler in one of the local dailies, vilifies the non-official profession as a whole, by asking, "Should or should not a medical certificate be countersigned by a Presidency Surgeon?" And this anonymous personification of duplicity answers: "It appears to me that there can be but one answer to the question, and that is, most certainly yes." (This refers to the certificate of a private practitioner given for a law suit). Now the orientalism of this pseudo-Anglo-Indian are too well known to escape detection. A sneak is a sneak always, and he is often like his prototype, "the father of lies," in every particular. This Judas is Mosaic in name, though not Hebraic in religion, if the latter virtue enters into his moral constitution at all. We seriously doubt it. For to start with, he heads and tails his letter to the lay press with A LIE. His quotation from the *Record* of the 1st June as to the heading of the article concerning "A Public Prosecutor making mistakes"—which by the way, is the correct heading of our article—is wrong, and this our sneaking reviler knew only too well, for he is a careful reader of the *Record*, even down to our "Notices to Correspondents," a word or two in the latter having in all probability excited his venomous spleen. To continue his untruthful and intentionally misleading fabrication, he painfully endeavors to induce the readers of the local daily (which has an official medico as a shareholder and penny-a-liner) to believe that in our editorial comment on the arbitrary and illegal action of the Public Prosecutor in regard to the medical certificate of a private practitioner, that the *Record* suggests and implies that the Indian Medical Association will be called upon to take action in the matter. Now no hint of any such movement finds place in our article, and to publish such a statement is a grievous perversion of the truth. We state in the article in question that "It is perfectly correct that the Government enacts that medical certificates granted to its own servants shall, before they are officially accepted, be either signed or countersigned by a Presidency Surgeon. Nowhere, however, in its Rules or Regulations does the Government enact, that in courts of law, certificates shall not be accepted when signed by qualified men other than Presidency Surgeons." The fact that Government has made no such law, is the correct answer to Judas' query, and if he in his sycophantic nature does not see the justice of the rulings of the State towards private practitioners in this particular instance, it can only be ascribed to the ascendancy of his own moral turpitude over those finer feelings that make a man, A MAN. The Devil often quotes Scripture and ofcourse, wrongly but cunningly, and so our would-be Anglo-Indian from Asiatic Turkey in a vain effort to quote pathology, mis-spells the patronymic of almost every bacteriological authority he quotes and even stumbles in the orthography of the old-fashioned Scotch name of LAWRIE. O tempora! O mores! Fie for shame! Thou "Ap-ke-waste" hero, thou turn-coat, thou scariot! Times out of number hast thou betrayed thy brethren. The existence of the "Associations" gripe thee, for thou hast not been trusted in "office" nor wilt thou be, for thou art well-known to be a WOLF IN SHEEP'S CLOTHING.

FINED FOR A WRONG DIAGNOSIS.

AN action has been tried in Dublin, which is of great importance to the profession, and apparently establishes a decision which will have serious consequences. The plaintiff was a shopkeeper named MASOX, and he sought damages from the defendant, DR. JOHN R. HANSEN, of Rathmines, for having negligently diagnosed an small-pox as a disease called *erythema nodosum*. The patient was one of the plaintiff's

employee; she was removed to Cork-street Fever Hospital, and the case was reported by the defendant according to the Act, as a case of small-pox. The plaintiff alleged that his business was damaged in consequence. Evidence was given that the case was not one of small-pox. For the defence it was pleaded that the words were privileged, and were written in compliance with the Notification Act, and in the belief that they were true. MR. JUSTICE MURPHY said the chief question to decide was whether the defendant had exercised fair and reasonable care and skill as a physician in advising that the patient should be sent to a hospital, and whether he reasonably and honestly believed that the girl was suffering from small-pox. The jury found for the plaintiff with £100 damages. The verdict is of so serious a character as affecting the position of medical men throughout the Kingdom, that an appeal should be made so as to settle the liability of a medical man once and for all.

THE PUBLIC PROSECUTOR WHO BLUNDERED.

THE *Indian Planter's Gazette*, commenting on our remarks in the case reported in our issue of the 1st June, says:—"We very willingly give prominence to an account of a disgraceful piece of high-handedness on the part of the public prosecutor, BAROO ABHUTOSH BIRWAR, of the Scaldah Police Court, which occurred during the progress of the Gonne Croft case, appearing in our contemporary the *Indian Medical Record*, and we entirely endorse our contemporary's remarks. We trust also that the matter will not be allowed to rest where it is at present, but that steps will be taken to represent the conduct of the Magistrate and the Public Prosecutor in a quarter from which redress is obtainable. If it is allowed to drop, suitors will be at the mercy of any jack-in-office who may choose to enunciate regulations of his own, and it is certainly a new and hitherto undiscovered quality in the indigenous Bengali pleader that he should be found to be a competent judge of the value of a medical diagnosis. If a man has to choose his doctor to suit the public prosecutor's fancy, the incidental troubles of setting the machinery of the law in motion will be increased a hundredfold."

OFFICER AND NO SOLDIER, LIEUTENANT-COLONEL AND NO DOCTOR!

A STORY is told of a young subaltern, who at a ball was addressed by a General as "soldier." He tartly retorted that he was "not a soldier, but an officer." "All right officer and NO SOLDIER," said the General, "how old are you?"

The youth might easily have been excused; but such snobbery in a grey-headed member of our profession is unpardonable, and shows the ridiculous effect of giving medical gentlemen high-sounding military titles. We quote from the *Anglo-Indian Recorder*:—

"A lady residing at an up-country station wrote to the military medical officer, who was, to boot, 'Civil' Surgeon of the station:—"Dear Doctor,—I am sorry to say baby has a gumboil; would you kindly call over and bring your lancet." She received in reply a memo to the effect that there was no such person as "Dr."—in the station; but she was equal to the occasion, and wrote again—"Dear Brigade-Surgeon Lieutenant-Colonel,—sorry to tell you baby has a gumboil, would you kindly come over and bring your sword!"

"PROFESSOR" VERSUS "LECTURER."

THIS is one of the wonders of this land, or at all events one of the things that it has been found difficult to satisfactorily explain. The moment a Commissioner L. S. A. is appointed to a chair in a medical college, he is forthwith transformed into a *Professor*; but all the jugglery, intelligence, or honest toil of an M. D. Assistant Surgeon, or of one however highly qualified, cannot raise him to anything more in name than a *Lecturer*. And how strangely indeed does fate favor the former. He may go week after week into a new chair and the

mantle of professional lore is supposed to descend upon him immediately he enters each new sitting. But when the Assistant is accommodated in any one of them, the star of brightness and of intelligence is immediately obscured to the official vision. Who can explain, and who will remedy the disagreeable phenomenon?

THE INTERNAL USE OF CARBOLIC ACID IN GONORRHOEA.

FEW diseases have been treated with so many drugs and with such disappointing results as gonorrhoea. DR. EDWARD BALM of Parbhani, since the past few months, gives 3 to 5 minims of carbolic acid in solution three times a day for this complaint and with satisfactory results, and he gives as a reason for adopting this line of treatment, that gonorrhoea is a specific disease depending on a specific bacillus, the gonococcus. Carbolic acid is an antiseptic and germicide. When given internally, it is mainly eliminated from the system by the urine, and it therefore acts directly on the bacilli. It also increases the flow of urine and allays the burning pain during micturition (dysuria). At the same time he uses a mild astringent urethral injection, such as two grains of sulphate of zinc to the ounce of water.

CHLORODYNE AS A PREPARATION OF PRUSSIC ACID.

FROM a medical point of view, and from the relative quantity of morphia that it contains, chlorodyne is more essentially a preparation of morphia than of prussic acid; but the Patent Medicine Vendors' Association lately prosecuted a chemist of Leeds (who sold chlorodyne) on the charge of "selling a preparation of prussic acid without registering the sale." The prosecution fell through, and the magistrate dismissed the case, as not only was the chemical evidence very conflicting as to the presence of prussic acid, but the maker also of the article testified that it did not and could not contain prussic acid, as none was added to this chlorodyne during or after its manufacture by him.

RETIREMENTS FROM THE WARRANT MEDICAL SERVICE.

ABOUT half-a-dozen Military Assistant Surgeons of the Madras Presidency are sending in their papers for retirement. Four of these are far from the age of compulsory retirement under the 55 years order. They are all men who were lent to the civil department, and who have, in consequence of military demands, been returned to military duty. This is a striking proof that the conditions of the Warrant Medical Service are highly unattractive. One of the warrant officers retiring thus early is within short reach of his seniority, and yet cannot make up his mind to remain in the service. When will the Government of India redeem its promise of improving the salaries of Warrant Medical Officers?

A PHYSICIAN MUST ALWAYS TRY TO SAVE LIFE.

IN connection with our recent remarks on this subject, we quote the *Lancet* :—"We cannot admit that even where we cannot relieve pain, we are one whit the less bound to preserve and prolong life. Man is a creature of such possibilities that the prolongation of his life for even a few weeks or months may have great importance, and although 'the laws of the realm may punish Christian men with death for heinous and grievous offences,' it is not yet recognised as part of a medical man's duty that he should take away that which he cannot give back."

P. M. O'S AND THEIR PAY.

WITH the approval of the Secretary of State for India, the Governor-General in Council is pleased to notify that the Principal Medical Officers of the four commands will be granted the rank of Surgeon-Major-General, subject to Her Majesty's approval in each case. It is notified that the con-

solidated salary of the Principal Medical Officer in each of the four Commands will be Rs. 2,200 per mensem.

The Principal Medical Officer of the Madras Army, who has been transferred to the Bengal Command, and the present Principal Medical Officer of the Bombay Command will, however, continue to receive their present rate of pay, viz., Rs. 2,500 per mensem.

CALCUTTA SANITATION. THEORY VERSUS PRACTICE.

SAYS our esteemed contemporary *Indian Engineering* :—"DR. SIMPSON admitted at a recent municipal meeting that Calcutta is yearly becoming 'more unhealthy.'" "It is my duty, (he said) to state that the long delay in the improvement of the sewer system is a great danger to the inhabitants." Everyone living in the city with a nose on him knows that. At the same time, if the Health Officer would condescend to get off his stiffs, and substitute work for theory, much might be done to ameliorate the insanitary condition of the city during the years that must intervene between 1895 and the adoption of a new drainage scheme."

THE DEATH-RATE OF CALCUTTA, AS COMPARED WITH OTHER CITIES.

THE Health Officer of Calcutta, in his report for the quarter ended on 31st March last, appends a comparative statement comparing the death-rate of Calcutta with that of London, Dublin, Glasgow, Madras and Bombay. During the whole quarter Calcutta shewed the highest death-rate. For the week ended 5th January the death-rates were London 17.4, Dublin 27.8, Glasgow 24.6, Madras 36.6, Bombay 28.8, Calcutta 42.9. For the week ended 30th March the rates were respectively 21.1, 47.4, 29.9, 30.2, 33.6, 66.5.

DR. WADDELL ON BUDDHISM.

A NOTABLE contribution to the history of Buddhism, and a work of unique interest, is Surgeon-Major WADDELL's new book, "The Buddhism of Tibet, or Lamaism, with its mystic cults, symbolism, and mythology, and its relations to Indian Buddhism." The author has had the advantage of exceptional privileges in the pursuit of his investigations, and his exposition of the ritual and beliefs of modern Lamaism may be taken as authoritative.

NEW INDIAN AND ANGLO-INDIAN SURGEONS.

The following Indians and Anglo-Indians have obtained the diplomas of L. R. O. P. & S. Edinburgh, and L. F. P. S. Glasgow :—William Scott, India; Henrietta Fraser Trall, India; Cecil Charles Murison, India; Arno Bhushanam Sreenivasa Charry Morrogh, Madras; Kaval Vittal Rao, Madras; Montague Rust, India; Gertrude Mary Hutton, Benares; Walter Hulbert Cox, Ceylon; Augustus John Laurie, Allahabad; Louisa Charlotte Nash, Bombay; Arthur Joseph Williams, Central India; Aloys Bance, Madras; Hermann Casey Venia, India; William Francis Macfarlane, India, Cyril de Vos, Ceylon; Rose Govindu Rajulu, Madras.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

We have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue :—

Robert James Owen, Asst. Surgeon, I. M. S., Chitral Relief Force, Camp Kanbat.

John Alexis Reardon, D.M.M.C., No. 65, Serangoon Road, Singapore.

Dominic Francis, Asst. Surgeon, I. M. S., Jask Dispensary, Persian Gulf.

M. Abdul Aziz, Senr. Hosp. Assistant, Mon Sing, Siam Boundary, via Mone, Burma.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

SHORT ITEMS.

At a meeting of the Rangoon Hospital Sub-Committee, it was decided to appoint a resident European medical officer to receive Rs. 200 per month and house, plus the salary of his gazetted Government rank. Plans were laid before the meeting for the proposed new General Hospital for Rangoon, which is to cost over eight lakhs.

Says the *Indian Planter's Gazette* :—" Dr. Hindmarsh, the planter's doctor to the Mouzafferpore District, returns from his English holiday next month. Dr. Moorehead, who has been acting for him, has earned golden opinions as an energetic, careful young physician, and should have no difficulty in picking up a decent practice after giving over charge."

The Inspector-General of Hospitals, Dr. Ross, has been advising H. H. the Lieutenant-Governor of Bengal that there is room for economy among the compounders and dressers of the Mayo and Howrah Hospitals, and among the menial servants of the Sukea Street Dispensary, and Sir Charles Elliott agrees with him.

The report of the lunatic asylums of Bengal shows that in 20 per cent of the cases, lunacy was traceable to ganja smoking. This is at variance with the finding of the Hemp Drugs Commission. But of course, ganja yields revenue, and who will dare to slay the hen that lays the golden eggs!

The Maharaja of Patiala applied for a European medical officer to carry out a thorough investigation into the fevers from which his subjects suffer almost every rainy season. Surgeon-Major Ronald Ross, of Madras, has been selected, and Patiala bears all expenses.

The Emperor William instructed the Berlin Academy to propose the name of M. Pasteur for the Prussian Order of Merit. Unfortunately the French savant's patriotic conscience is too sensitive, and on being sounded on the subject, he has declined the honor.

A man died the other day in New York after licking an envelope. He was poisoned by decaying animal matter from the glue getting into a sore in his mouth. No poisons are more deadly than those produced by the decay of animal matter.

During the illness of Surgeon-Captain Stalkart, A. M. S., Assistant Surgeon G. O. Forrest takes over medical charge of the Fort Station Hospital, and the troops in the Allahabad Fort, in addition to his other duties.

Mrs. Alice Van Ingen, M.D., Brux., L.S.A. Lond., has been appointed to the medical charge of the Kotah District under the Dufferin Fund Service, on a salary of Rs. 500 per mensem with residence and carriage allowance.

Sir Charles Elliott hopes that the lessons of the recent epidemic "will not be lost upon the Corporation of Calcutta."—a hope which will be widely echoed, albeit somewhat a forlorn one.

The Scotch papers by the last mail contain long notices of the death of Dr. Cleghorn of Strathvillie in Fifeshire, who, with Sir Dietrich Brandis, has the credit of introducing scientific forestry into India. He retired in 1869.

Commend us to Akyab for public-spirited officials. The branch Dispensary there was mainly built by Assistant Surgeon Mung Tha Na, A.T.M., who contributed Rs. 3,000 out of Rs. 8,500 of its entire cost.

The Madras Government has directed that all male leper convicts sentenced to imprisonment shall be confined in the Criminal Ward of the Leper Hospital, Madras.

Surgeon-Major General Robert Harvey, M.D., F.R.C.P., D. S. O. has just had the honor of D.L.D. conferred on him by his alma mater, the University of Aberdeen.

The buildings of Charing Cross Hospital, London, are to be sold, and its School and Hospital are to be rebuilt in the suburbs.

Deputy Surgeon-General Joseph Ewart, M.D., formerly Professor of Physiology in the Calcutta Medical College, and thirce Mayor of Brighton, has received the honor of Knighthood.

Dr. Edwin Hindmarsh, Surgeon to the Tirhut Planter's Association, has obtained the diploma of F.R.C.S. Edinburgh, by examination.

Mr. Silk, C. E., an officer of some sanitary experience, succeeds Mr. Kimber as Sanitary Engineer to the Calcutta Municipality.

The Travancore Government has applied to the Secretary of State for India for a medical Officer to fill the vacancy caused by the death of Dr. Innes.

Mr. B. L. Dhingra of Lahore has passed the final examination in Forensic Medicine and Midwifery for the diploma of L. S. A. London.

It is exceedingly gratifying to the medical profession to learn that Surgeon-Major Robertson, I. M. S., the hero of Chitral, "that brave civilian," is to be knighted.

It is also very pleasing to find that the gallant services of Surgeon-Captain Whitechurch, I. M. S., are to be rewarded with the Victoria Cross.

The number of patients admitted to the Darjeeling Eden Sanatorium last year—349—was smaller than that of any previous year, but the income increased by 16 7 per cent.

Dr. Jogendra Nath Ghose has been elected a Municipal Commissioner for one of the wards of the City of Calcutta.

Dr. Lawrence Fernandez has been elected a Municipal Commissioner for one of the wards of the City of Calcutta.

A General Hospital for contagious diseases for all native troops at Peshawar is sanctioned.

Mr. W. H. Reed of Bombay has passed in Midwifery the Examination for the L. S. A. Lond.

Surgeon-Major J. H. Tull-Walsh, I. M. S., has obtained the diploma of F. R. C. S. Eng.

Mr. Dinsha Rabansha Dalal, of Bombay, has obtained the diploma of M. R. C. S. Eng.

The Viceroy thanked Dr. Robertson personally at Simla for the excellent work done by him during the siege of Chitral.

It is with deep regret we record the death of the Revd. J. L. Phillips M.D., a noble physician and a heroic Sunday School worker. He died last week at Mutucorie from Bright's disease.

Current Medical Literature.

MEDICINE.

The Relations of Variola, Varioloid and Vaccinia.

GEORGE DOCK EYRE, M.D., points out that while the followers of JENNER contend that the vaccine variety of the virus never changes back into that of small-pox, CHAUVEAU, CROOKSHANK and more recent specialists and the majority of observers maintain that vaccinia is only disguised small-pox, which may at any time recover its primitive qualities and produce the more severe disease either in the subject himself or in another person attending him, and then become the starting point of a severe epidemic; and THOMSON and KAPOSI show that varioloid is a mild form of small-pox occurring in both vaccinated and unvaccinated persons. The view that vaccinia is a totally distinct disease from and yet nevertheless protects against small-pox is not often advanced now, as the various epidemics have seriously taught that vaccinated persons may have small-pox in all possible degrees of severity, while there are thousands of instances where unvaccinated persons have exhibited a marked resistance to the infection. This natural immunity may be the result of intra-uterine variolation (DUBREUILH) or of prolonged residence in an infected place (COLIN), but the statistics (1746 to 1821) of the London Small-pox Hospital point out that this immunity varies from 7 to 30 per cent. while WOODVILLE places it at 5 per cent. in adults and 1.6 per cent. for infants and DESOTEAUX and VALENTIN estimate it at 0.1 per cent. for all ages; but most authorities agree that this immunity is easily lost, and persons who have passed unscathed through many an epidemic may succumb at a later period, while JENNER maintained that vaccination afforded permanent protection. BROWN, BRYCE, COPLAND and GREGORY found that the protection diminished gradually after the second year; but KLAMANN (1893) NEUMANN, WITTHAUER and PREIFFER are of opinion that the period may not exceed one year and that even an attack of confluent small-pox does not necessarily protect against the recurrence of the disease.

Even to the present day vaccination fails to protect in thousands of instances, making it a matter of solemn regret that after a full century of investigation and millions of inoculations, the true pathological relation of vaccination to small-pox should be so obscure as to make it a matter of serious doubt, whether small-pox is caused by protozoa, amoebae or rhizopods, or whether the *cytocytes variolae* were spurious instead of genuine parasites; or again, whether the most truth lies in the theory that "the contagium does not change, but the cells of the host cause the effect of the contagium to develop in different ways," as the most eminent bacteriologists of the present day have proven, times without number, that neither vaccination nor re-vaccination nor even a prior attack produces immunity for indefinite periods of time, though variola and the animal poxes mutually representing each other, immunity against one excludes infection from the other, and a single transfer of the virus may cause immunity for some or many years, both against inoculation and against all human or animal variolous diseases, yet the consensus of opinion is that the immunity, real or expected, is by no means uniform or positive in all cases alike, while one and the same infection causes: variola vera, purpura variolosa, variola hemorrhagica, varioloid, varioline and vaccinia in man; horse-pox and equinia in horses; and local cow-pox and vaccinia in kine.

Alimentation in Febrile Disorders.

DR. E. A. DAY points out that patients often die not for the want of proper medication, but from the need of suste-

nance, because in all febrile affections the system often interferes with the proper assimilation of nutriment by bringing about a morbid condition of the salivary, gastric, pancreatic and intestinal glands whose function is to produce the various digestive fluids and ferments, and while there is an increased waste and destruction of the tissues of the body, a vicious circle is formed by the excretories being compelled to do the double work of eliminating the increased tissue waste and disposing of the food which the food that the impaired digestive and assimilative organs are unable to utilize: consequently the system becomes surcharged with effete matter to such a degree as to exaggerate the fever and produce a high disgust for food which is vomited as soon as swallowed, and the stomach practically or absolutely ceasing to be an avenue through which sufficient aliment, to maintain the vital powers through the crisis of the disease, may enter the system the patient dies of exhaustion. Although not enough to be relied upon of itself, he thinks it probable that sufficient nutriment to help the resistance to exhaustion (when stomach feeding is impossible by virtue of deranged digestive powers) can be introduced through the integument; but the case must be closely watched and if necessary, assisted by nutrient enemata.

A Mother infected with Primary Syphilis from her own Syphilitic Child.

COLLES rules that a mother cannot be infected by her own syphilitic child, but a different tale was told by a woman of 31 who, during 13 years of married life, had had 8 children and no miscarriages. Of the 8 children 3 died in infancy; while, with the exception of the baby, the others were in good health. Complaining of ulcers on her breast, she was examined by Senior Assistant Surgeon A. LUCAS, F.R.C.S., who found that the ulcers, which had all the characteristic signs of "hard" sores, were situated about ten inches away from the nipple, and extended nearly two-thirds round the breast. The eight months' baby that she was nursing had snuffles and the *cafe au lait* complexion, condylomata on the anus and in the mouth, there were ulcers that had appeared, when the child was six months old. The ulcers on the mother's breast had appeared a month later, and careful enquiry showed that the infection was from her child, and not from her husband, who was perfectly healthy. She was treated with blackwash and hydrarg. c. creta under which the chancres began to clear up; but a secondary rash appeared on her arms and chest, and she had some pharyngitis. Unfortunately she stopped further treatment and observation by ceasing to attend the hospital.

Acromegaly.

ARNOLD, who attaches great importance to the relation of pituitary and thyroid diseases to changes in the nerve centres, the peripheral nerves and their muscles, inveighs in favor of more experiments towards attaining accurate information. He thinks that the *osteo-arthropathies* associated with or following lung, syphilitic and vascular affections should not be confounded with true acromegaly, which is an independent disease, presenting characteristic muscular and nervous lesions peculiar to itself, and not to be found in any of the others, for instance: All varieties of fibre degeneration of the muscles, hyaline degeneration of the nerve vessels with thickening of the pericellular capsules and pia of the cori, and a thin layer of myelin fibres; vacuolation of some of the nerve cells; obliteration of the central canal of the spinal cord by gliomatous growths; degeneration of posterior roots of cauda and lumbar cord, and in the columns of Goll and the pyramidal tract; enlarged hypophysis; thickened meninges and softening, sclerosis and pigmentation of the brain matter; naked eye enlargement in the cervical sympathetic and the thyroid, which is considerably enlarged, and contains several colloid masses.

Persistent Recurrences of Influenza.

Parkeus tells us that the greater virulence of the pathogenic germ is commensurate with the greater contagion towards producing an epidemic of influenza from which there is apparently no immunity against recurrence, even though nothing occurs in the interval between the different attacks. Looking closely into the matter, he finds that instead of conferring immunity, the first attack of influenza often predisposes the patient to a return of the disease, suddenly and at any time. He has known the disease to attack the same organism from two to four times in a period of from 30 to 120 days, (each time with more or less prolonged intervals of complete apyrexia) and thinks that these repeated attacks should be attributed to a series of autochthonous re-infections in a soil especially favorable to them.

Intestinal Antisepsis in Children.

WHILE laboratory experience teaches that many of the older drugs in which we place most confidence are of service by virtue of their antiseptic properties, DR. J. COMBY points out that the digestive tube is a laboratory of poisons which, under healthful conditions, are eliminated by the natural excretories, and particularly by the kidneys, and if the renal function be impaired, toxic material accumulates in the blood. Without dwelling upon the advantages of buccal antisepsis in various disorders, he points out that in all maladies of the gastro-intestinal canal—from the mouth to the anus—insoluble antiseptics are particularly required in the therapeutics of childhood, and in choosing from drugs of this class, he advocates in favor of benzo naphthol, salol and betol and the salicylate, subgallate and subnitrate of bismuth, supplemented by occasional lavage of the stomach and irrigation of the bowel.

SURGERY.

Methods of Teaching Surgery.

IN these days, when there is a tendency to reduce the time given to systematic lectures and increase the number of the teaching staff to the detriment of obtaining anything like uniformity of views in collateral or sub-divisional subjects, the questions naturally arise as to *what* is to be taught as surgery, *how* it is to be taught, and to *whom*? Considering that students may be divided into three classes: (a) those desiring to be general medical practitioners; (b) those specially fitting themselves for surgical work; and (c) those wishing to learn only as much surgery as will scrape them through the M. D. examination, DR. JOHN S. BILLINGS thinks that a good deal depends upon what the student is required to know of anatomy and pathology before he begins his surgical studies, the time at his disposal and the nature of the final examination, the local condition and the character, tastes, and teaching-powers of the different men who make up the faculty, together with the facilities for laboratory and clinical instruction. Clinical instruction, he admits, would be the best mode of teaching surgery; but, as clinical material is not available to cover the entire field for any school, no matter how large its hospital and dispensaries, systematic didactic teaching must come to the assistance of clinics, and these again must be supplemented by recitations, demonstrations, practical operation on dummies, animals and cadavers in the details of treatment of wounds, bandaging, dressings and major and minor operations; theoretical clinical lectures, illustrated by operations in a well-lighted and properly graded amphitheatre and practical clinical instruction to ward classes in which each student is required to do something in the diagnosis or treatment or both. He urges strongly the necessity for a good

grounding in surgical anatomy and pathology, and while objecting against the present system of lengthy lectures and too many class sub-divisions with consequent waste of time by repeated repetitions of the same preliminary bases, by too many teachers, of hardly necessary splitting up of the subject of surgery into orthopaedic, ophthalmic, abdominal, genito-urinary, *et cetera* surgery, he very rightly points out that as "what the students hear and see during the first half of a lecture is what they will make the best notes of and remember best," the lecturer should *do* in his mind the half-hour dozen questions or so that he would put to test the student's knowledge of the subject he is going to speak on, and then proceed to explain (*i.e.*, answer) these questions as clearly definitely and fully, and in as few words as are compatible with making the object in view understood and appreciated. Another good plan is, to from time to time test the knowledge acquired by the class by suddenly picking upon any one of the students to lead a debate by his class mates on any portion of the subjects previously lectured on and requiring him (or those who differ from his views) to give reasons for the statements he makes.

Cardiointesis, Endocarditis and Pericarditis with effusion. Accidental tapping of right Ventricle after apparent death: Recovery.

LAST May, a fairly healthy young lady, aged 19, had a severe attack of erysipelas, which had apparently yielded to iron and applications of ichthyol and lanoline; but on the 5th day a severe attack of rheumatic fever suddenly developed. The temperature, which varied from 99° to 103°F, showed a distinct tendency to an evening rise, and the pulse, which was of fair strength, regularity and volume, varied from 100 to 116 per minute, but a well-marked friction was audible over the whole base of the precordial area, and she complained of persistent effusion about the chest. She was given large doses of salicylate of soda, and sinapisms and warm poultices were applied locally, under which the 'friction' abated and the fever decreased, but there was no diminution in pain. On the 24th day there were occasional attacks of sickness; swallowing was difficult, movement of lower limbs caused excruciating agony; pulse became feeble, dicrotic and varied, from 120 to 140 per minute; respirations reaching 30 to 50 per minute; irritable hacking cough; cardiac dulness greatly increased; friction was still audible, but the heart sounds were distant, feeble and obscured, and she grew worse hourly. On the 32nd day the pulse suddenly slowed down to 80, then becoming uncountable and almost imperceptible, together with other symptoms of approaching death; 30 minims of ether were injected into her arm and a second 30 into her left breast, but as the heart and respiration suddenly stopped, DR. ALLEN T. SLOAN jumped up, seized the aspirator and plunged the needle into the 4th interspace, a little to the left of the sternum, and a trifle below the left nipple, when to his horror 8 or 10 ounces of pure blood gushed into the aspirator bottle (then suddenly stopped) and shewed him that he had accidentally penetrated a cavity of the heart. Thinking "all was over," he was about to withdraw the cannula, when the heart suddenly re-asserted itself in the race for life and the patient seemed to recover from a painless death to die one of terrible agony, considering her screams and sufferings. She was kept well under the influence of ether, then injected with $\frac{1}{4}$ grain of morphia, absolute rest was enjoined with liquid feeding in the shape of strong soups flavored with vegetable juices, bowels moved by glycerine enemata, and on the 51st day she was pronounced convalescent.

Splenectomy.

THOUGH practically a modern operation, splenectomy dates back to the sixteenth century, when ZARCAINI made the first unsuccessful total extirpation in 1549, and FERRERIUS obtained similar results in 1711, while DIXON, writing in 1738, speaks emphatically of a "society of surgeons" who acquired notoriety by "wauling" their patients (*wult* meaning spleen), but it was not till 1867, when PEAN removed an enlarged cystic spleen from a young woman that the operation was accorded a place in legitimate surgery. FRAUOLINI (1881) was the first and only one who (ever) successfully extirpated a spleen for leucæmia; but AGNEW (1889) maintains that all cases of hypertrophy, whether simple, malarial, or leucæmic, are excluded from the realm of operative surgery, yet RIGGERS (1892) is the only successful extirpator for a subcutaneous trauma of the spleen. Though the indications for splenectomy have not been definitely settled and removal of the spleen for cystic disease gives an excellent record, most authors advise preliminary incision and drainage, and think that in all cases it is better to tap and drain than to extirpate the spleen. DR. W. J. CONKLIN declares that while it is unjustifiable to operate when the white blood corpuscles are in excess or in leucocytæmia or other conditions with extensive enlargements of the lymphatic glands, splenectomy is directly indicated in movable or displaced spleens; severe traumatism with or without an external wound; prolapse of the spleen into a parietal wound; protrusion after injury; tumors, simple hypertrophies and other splenic enlargements that have resisted most other measures—and though the shock may be profound or the hemorrhage profuse, the danger may be averted and sepsis guarded against by prompt, quick and clean work, and in any case total removal of the spleen is certainly preferable to mere replacement or operative fixation.

Filling the Roots of Decayed Teeth.

To fill a tooth and leave a vent (*i.e.*, rhizodontology), declares MR. EDMUND OWEN, is to only roll a stone over a whitened sepulchre, as dead teeth exist in two conditions, in one of which the root membrane is healthy and in the other it is not. In the first group the cavity of decay having been excavated, the root canals and pulp cavities are thoroughly cleaned, rendered aseptic, dried and immediately filled with some indestructible material, at the one sitting; but in the other group the filling must be delayed until the diseased condition of the root membrane has been removed by both constitutional treatment as well as by the judicious application of strong antiseptics, such as hydrogen peroxide or corrosive sublimate, after which the cavities can be cleaned and effectually plugged with permanent filling. Whereas to fill a decayed tooth that is charging pus either through a fistula or via the pulp canal, or to try to establish drainage by drilling into the pulp cavity, is utterly opposed to surgical principles, as the vent which forms the outlet, also forms an inlet while sealing up the outlet, or a discharging sinus, or an actively carious tooth may be attended with immense danger to the patient.

The Implantation of an Artificial Testis after Castration.

BEING compelled to castrate a man 37 years of age for tuberculous involvement of both testes, DR. R. F. WEIR tried to humour his request "to not completely remove the right testis" by, (at the close of the castration), resorting to an expedient to relieve his mental anxiety. Thoroughly removing the whole of the diseased right testis and scraping the left one, he implanted on the right side in the half-vacant scrotum, a properly disinfected ball of celluloid of one inch diameter and closed and sutured the scrotal wound. Healing promptly followed and the patient has worn this artificial testicle

since May 1899, without complaint. DR. J. B. BARNES reports a similar case in which, however, gutta serena takes the place of the celluloid.

To see Cataract in your own Eye.

Drive a pin hole through the middle of a visiting card, and holding the flat surface of the card towards the light in the direction of a piece of blue sky, place the eye close to the hole and look through, when you will see a fairly large but faintly illuminated field or *clear* disc should your eye be normal, but if you have a cataract, it will be projected upon the field. In this manner you can delineate your own cataract, watch its progress, and decide whether you will have it operated on; for by looking through the hole in the card, as writes J. S. in *Knowledge*, you are in reality observing the shadow cast by your cataract on the retina at the back of your eye.

OBSTETRICS AND GYNECOLOGY.

Treatment of Endometritis.

DR. BACON's method of meeting its indications consists in:—
(1) Removal by curettage, drainage, irrigation or swabbing of gravidital or menstrual decida which afford soil for bacteria and their toxins and secretions (2). Destruction, (after curettage of outer portion of the endometrium), of pathogenic agents by direct application of caustic or strong antiseptics, (3) Stimulation, by massage, with Dolores's ecovilon or ordinary applicator swab, of the bactericidal and resisting properties of the tissues. (4) Stimulating nature's antiseptic properties by improving the circulation, controlling the distended capillaries and arteries, emptying the lymph-channels and removing the exudations and extravasations of serum and blood; but it is difficult to correctly understand how nature exerts this antiseptic power, whether by phagocytosis, antitoxin of blood serum or any other cause.

Rules for introduction of Instruments into the Uterus.

Do NOT, advises DR. C. S. BACON, examine a patient at her first visit, but teach her how to use the vaginal douche with corrosive sublimate for 3 or 4 days, after which—
(1) Wash your hands and instruments thoroughly with an antiseptic. (2) Treat her external genitals and the surrounding skin likewise. (3) Thoroughly scrub every part of the vaginal walls with liquid soap and then wash out with a solution of lysol or creolin. (4) Introducing a NEUGERBAUER speculum scrub the cervical canal first with liquid soap, then strong creolin solution, and lastly alcohol. (5) Never introduce an instrument without seeing the cervical canal; and if immediate examination be necessary, do so either in a hospital or at her own home with all the preparatory details of an aseptic surgical operation.

Hemophilia at the onset of Menstruation.

OLIVIER has reported the case of a girl, thirteen years old, who had just menstruated for the first time, the discharge at first being slight, but subsequently becoming so profuse as to threaten life. All other measures failing, the vagina was tamponed and the flow was moderated. Upon the removal of the tampon, at the end of twenty-four hours, the hemorrhage was resumed with its previous freedom. Vaginal injections of hot water were employed and followed by the introduction of a tampon, but without success.

Upon consultation, the conclusion was now reached that the girl was a hemophilic. It was learned that when a child, she had fallen, injuring the head, and a large ecchymosis had formed beneath the scalp. The removal of teeth at different times had also always been followed by free bleeding.

The following plan of treatment was outlined: 1st, vaginal injections, at a temperature of 122°, every two hours; 2nd,

If the hæmorrhage persisted, gaseous-oestria, intra-uterine application; of 50 milliamperes, followed by a tampon; 3rd, treatment directed toward the general condition, especially alcohol, in some form; 4th, the hourly administration of hydrastisina. In this way it was hoped to control the immediate bleeding. The question also arose as to its repetition in the future. The removal of the ovaries in the hope of obviating such repetition was contra-indicated by the danger of fatal hæmorrhage from the operation.

The after-treatment of Laparotomy.

DR. BRICKEK (Wursburg) said that formerly opiates were invariably given after laparotomy, but that at present even laxatives were prescribed in order to remove pyogenic bacteria and their products. Opiates should not be given after simple operations, but they were useful in cases where the intestines were irritated or loosened during the operation; also when symptoms of slight ileus appeared opiates should be tried at first, and if the symptoms did not disappear very soon the peritoneal wound should be opened up. Hæmorrhage and peritonitis after the operation also require the peritoneum to be re-opened.—*Lancet*.

Vaginitis in Children.

TINCTURE of belladonna, 1½ fluidrachms (8 grammes); spirit of nitrous ether, 3 fluidrachms (12 grammes); Cammorrated tincture of opium, 5 fluidrachms (16 grammes); tincture of buchu, sufficient to make 3 fluidounces (90 grammes). Mix. Dose: Half a teaspoonful, increasing to a full teaspoonful, in a little water, every two or three hours. Give 20 to 30 grains (1·3 to 2 grammes) sodium bicarbonate after each meal, with flaxseed-tea or other demulcent drinks.—HOMER C. BLOOM, Philadelphia Polyclinic.

Death from and after Post-Partum Hæmorrhage.

TARNIER teaches that flooding after the application of the forceps must always be expected, since the instrument is usually employed because of uterine inertia, a source of hæmorrhage. The danger comes when the placenta is expelled. TARNIER, when called to apply the forceps for a colleague in private, used to leave before the delivery of the placenta. In consequence he was very often called back. He makes these observations in respect to a robust woman who suffered from uterine inertia, and was delivered by forceps. There was considerable flooding, but not so much as to lead to expectation of bad results. The patient went to sleep, but awoke a few hours later and complained that she was suffocating. There had been no fresh hæmorrhage. She very soon died. At the post-mortem examination miliary tubercle was found disseminated in abundance over the lungs, pleura, liver, and spleen. There was no evidence of insufficient blood in the system, no embolism, and no blood retained in the uterine cavity. The previous flooding, quite insufficient to harm a sound constitution, proved enough to kill this patient. Yet externally she looked healthy. We must be slow, says TARNIER, to find fault with a colleague for losing a patient after flooding. Had the above case occurred in private, and no necropsy held, the obstetrician would certainly have incurred more blame than he deserved.—*B. M. J.*

Uterine Hæmorrhage.

DILATE the uterus without *okloroform*, curette, and pass a fenestrated sound into the uterine cavity, containing a metal tube of small calibre. Connect this with an apparatus giving off steam at about 212°F. (100°C.), turning off the steam in one minute, when hæmostasis will be complete. The patient feels no pain, the part becomes insensative, fœtor is destroyed, and the mucosa membrane is covered with a thin albuminous pellicle.—ZACHARIN, *Univ. Med. Jour.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Dead Brain Action.

A CURIOUS case reported in a contemporary recently opens up a number of most interesting psychical problems. The patient, a Welshman, forty-seven years of age, appears to exist, like Messrs. JERTIL and HYDE, in two separate and distinct states of consciousness, the right and the left brain exerting alternately a preponderating influence over the motor powers. In the two mental conditions, which are very marked, the patient speaks a different language, English or Welsh. In the English stage he is right-handed and is presumably using the left cerebral hemisphere; he writes, talks, and understands English only, is restless and mischievous, bold, fierce and fairly intelligent, and appears to be the subject of chronic mania. In the Welsh stage he becomes left handed, and is probably using the right cerebral hemisphere; he writes and speaks, and understands Welsh, but not English; he is shy and suspicious, does not know coins or tobacco, of which he is very found in the English stage, and he is clearly in a condition of dementia. Sometimes the one stage seems to merge gradually into the other, and in this intermediate condition he can use both hands equally well and employs both English and Welsh words. The man lives, it seems, two separate existences, but the mental impressions of each existence are recorded in one cerebral hemisphere only, at a time. It would almost appear, therefore, from this case that each hemisphere has the power of acting independently of the other, and that in health, the customary co-ordination in movement is the result of education and experience, rather than of any controlling influence of one side of the brain over the other.—*Lancet*.

Decomposition in the Intestines.

POHL has shewn that milk, and HINSCHLER that carbohydrates, diminish the amount of fermentation in the intestines; WINTERNITZ, however, thought that the milk diet acted chiefly by means of carbohydrates contained in it; ROVIGHI, on the other hand, that its efficacy lay in the lactic acid.

SCHMITZ estimating the fermentation in the bowel by the amount of ethereal sulphuric acid passed in the urine, found that milk sugar had no effect in dogs. Fresh cheese, which contains a very small quantity of carbohydrate material, checked the intestinal decomposition of protekis very vigorously; in fact, in one experiment the putrefaction appeared to be nil. What constituent of the cheese had worked this wonder? It could not be its antiseptic action, for it had none. It was not the casein, for pure casein had no effect. The cheese sterilised, acted as strongly as before, it therefore was not due to the organisms contained in it. He concluded that it must have been the small quantity of carbohydrate contained in the cheese. Observations on men gave the same result.

IN another experiment he found that in men HCl by the mouth decreased intestinal putrefaction; in dogs it had no effect. That is to say, that in dogs a state of hyperacidity is present, increase of which does not affect the organisms ingested, while in men HCl is required to be given to give the gastric juice a bactericidal action on those organisms which flourish in the intestines.—*Practitioner*.

Accessory Spleens.

ALBRECHT shewed a specimen before the Vienna Society of Physicians, in which there was an enormous number of accessory spleens. These seldom exceed thirty to forty, but in this case there were countless numbers, some being only the size of a pin's head and the largest that of a hazel nut, except in the normal position of the spleen, where there was one as big as a walnut, having a splenic artery and vein arising in

the normal position. The most remarkable point was that they were not confined to the mesogastrium, which is the generally accepted site for the development of the spleen, but were present over the whole peritoneum (for example, on the convexity of the liver). They had a normal splenic structure, but in some there was a great quantity of pigment. The specimen was taken from a patient, aged 25, who died of chronic parenchymatous nephritis. No such case has been reported.—*B. M. J.*

Diagnosis of Diabetes and Glycosuria by Examination of the Blood.

DR. BREMER describes a modification of EHRLICH's method of staining cover-glass preparations of blood with eosin and methyl blue. By this method of staining, in normal blood the red blood-corpuscles appear brownish red, but the color varies from a clear reddish brown to a deep chestnut brown (*The British Medical Journal*). The nuclei of the leucocytes stain blue. BREMER found that in diabetes and glycosuria the red blood-corpuscles either remained completely unstained, or they were simply tinted light yellow or greenish yellow. Only occasionally a small peripheral zone of the red corpuscle was tinged slightly red. Other minor changes were found in the leucocytes. With acid fuchsin and other so-called acid dyes, the red corpuscles of diabetic blood stained just in the same manner as those of normal blood. It was only eosin which did not stain them. In order to determine whether this loss of staining affinity for eosin was due to the abnormal amount of sugar in diabetic blood, BREMER treated cover-glass preparations of normal blood with a solution of sugar. But he found that the red corpuscles still stained with eosin, as in normal blood. If, however, a cover-glass preparation of non-diabetic blood was floated for twenty-five to thirty minutes in a diabetic urine, the red corpuscles failed to stain brownish red with eosin; they remained unstained or were only slightly tinted yellow or greenish yellow, as in diabetic blood. But the red corpuscles in a cover-glass preparation of non-diabetic blood, treated with urine free from sugar, stained well with eosin. In glycosuria produced artificially by the administration of phloroglucin for three days, the red corpuscles failed to stain with eosin, as in diabetes.—*N. Y. Med. Rec.*

Gonococci in the Vaginal Secretions.

BUTNER, in the space of three months, examined fifty-four prostitutes of Dorpat, to ascertain whether or not they were affected with blennorrhagia. Of these, thirty-two were subjected to a semi-weekly examination through the speculum; the other twenty-two were encountered in the hospital. Of these latter, in only six did microscopic examination shew the presence of a blennorrhagia. In eleven of the remaining sixteen, or 68 per cent., bacteriologic examination shewed the presence of the gonococcus in the vaginal secretion and the same result in nine, (28 per cent.), of the prostitutes registered by the police. Among the prostitutes under treatment in the hospital, BUTNER made a separate examination of the vaginal secretion, the cervical mucus, and the secretion from the urethra. In the eleven women with manifest blennorrhagia he never found the gonococcus in the vaginal secretion. This microbe was found six times in the cervical mucus and the urethral secretion at the same time; four times in the secretion from the urethra only; once in the cervical mucus only. The author concludes that the examination of prostitutes, as it is practiced at present, does not give sufficient basis for the establishment of a certain diagnosis.—*N. Y. Med. Jour.*

A new variety of the *Bacillus Anthracis*.

CHAUVEAU AND PHILALIA, in experimenting on guinea-pigs with cultures of the *bacillus anthracis*, attenuated

by the action of compressed oxygen, have discovered cultures disclosing a new variety of this microbe, which they name the *bacillus anthracis claviformis* because of its key-like or bell-clapper-like form. This organism is permanent and specific in its form, and physiologically is distinguished by its total want of virulence in all but very large doses. It also possesses only the feeblest immunitary power, and neither this nor the original virulence of the anthrax bacillus can be restored to it by the usual procedures.—*B. M. J.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The origin of Hospitals.

IN contradiction of the claim that hospitals were exclusively the result of Christian teaching, GATEWOOD forcibly points out that BERDET proved that as early as B. C. 400, medicine had reached a very high degree of perfection in Egypt, but being confined to the priests only, who carefully guarded the secrets of the healing power, it became almost a "lost art" for many years after the conquest of Egypt, and the wholesale destruction of her temples and priesthood. Warlike Sparta had hospitals attached to her training schools in B. C. 800; and in Athens and India, where medicine and religion sailed yard and mast, we frequently read that in B. C. 600 to B. C. 500 large hospitals were raised in the form of temples and shrines, where the sick presented offerings to the gods and put themselves under the care of the priests. During the earlier days of the Christian church, the care of the sick was the special duty of the Christian clergy, and from CHARLEMAGNE'S time to A. D. 800 monasteries and hospitals were synonymous but gradually separating and developing independent of each other, the term "hospital," as it is now understood, is of comparatively recent date. From A. D. 600 to 1750 is recorded as the period of Auto-da-Fe, demoniacal possession and witchcraft while from A. D. 1750 to 1850 is designated as the period of brutal suppression, cruelty and ill-treatment, and it is only lately that hospitals were built where systematic treatment could be obtained. With the strides that medicine is at present making, the time is not far distant when lunatic asylums shall cease to be mere detention houses for those mentally unsound, and properly conducted hospitals will be opened where the insane person shall be a patient as truly and surely as the one who is suffering from bronchitis, typhoid, syphilis, &c.

Individual responsibility in the prevention of the spread of infectious disease.

WHILE charging the grand jury at Patterson N. Y. Assizes, Judge DIXON informed them that the United States Laws provided the criminal indictment as a public nuisance, of any person who (a) knowingly communicates a contagious disease to another; (b) recklessly endangers the health and lives of others by carrying about with him the germ of a contagious disease; (c) spreads the disease by conscious exposure thereto of others by his presence in public places. If death occur through such carelessness, he may be indicted for manslaughter; but whether any consequences follow the above offences or not, he may be indicted and punished as a public nuisance for endangering the public health.

Remuneration of Medical Witnesses.

SOME seventy years back, when a guinea had nearly eight times the commercial value it now represents, the daily fees arranged for medical witnesses, who were required to give evidence, were:—Treasury prosecutions 3 guineas, Police Court 11 shillings, Sessions or Assizes 4 guineas, Coroners Court 21 shillings, besides first class passage; 3 shillings

for eight years, although, for every night he remained away from home. Though the fees hold the same, the travelling allowance is struck down to second class, and the Sunday, interlocking staffing, and eight ministrations are disallowed. The Police Surgeon's Association, we are informed, contemplates bringing these matters before the Home Secretary, pointing out that while the *Crown* pays very inadequate fees to its witnesses, it cannot engage to secure the best talent; and what it orders as payment, is more than frequently a mere trifle compared with what is offered to medical witnesses for defence. We wish the Association every success, and suggest that its proposals might be extended to India also.

An Automatic Gallows.

THE new hanging machine that is to be tested at Connetquot is so built that the moment the condemned criminal steps on the lethal platform his weight sets in motion the necessary machinery for his suspension. The employment of the apparatus has been protested against by some persons who argue that the man thus executed is virtually a suicide, and the STATE has not the right to abet a *felio de se*.

—:O:—

THERAPEUTICS AND PHARMACOLOGY.

The Madar Plant and its Properties.

ACCORDING to the observations of J. H. BRIDGEMAN, this plant has marvellous properties, and is pretty largely used by the natives of India: *Nice* grains of the dried and pulverised root, given four times daily, and accompanied by a dose of castor oil on alternate days, may be considered a specific in dysentery; the oil obtained by boiling equal parts of the dried root and mustard oil together for an hour, forms a curative anodyne liniment for rheumatic and other pains, while the lesser roots are used as tooth brushes (*mis-wach*) for strengthening the teeth and gums and averting tooth-ache. The leaves are heated on an iron pan and then tied on to affected parts to assuage pain. The flowers are used as a specific in fever. The milky juice that exudes from any part of the living plant when bruised, is useful in bringing blind boils to a head and bursting them; it is used both internally and externally in splenic fever and certain forms of eczema, and is recognised as a powerful remedy in toothache, when in addition to removing the pain, it appears to have the property of eradicating a loose tooth and of strengthening a firmly fixed one.

Quinine as a Preventive of Malaria.

AT the instance of the Paris Therapeutic Society, a committee was named, a few weeks ago, to establish, for the benefit of the military authorities, the most preferable forms of administering salts of quinine as a preventive for malaria. The committee reports as a preventive, basic hydrochloride of quinine as the preferable salt, its solubility being sufficient, and, as it is richer in alkaloid, it is less irritating to the digestive organs than the sulphate. Hydrobromide appears preferable in troublesome fevers on which the hydrochloride has not had any effect. Quinine should not be used in a compressed form. Soluble pills or perles, in a gelatine envelope, appear to be the best preparations. Pills or perles, each containing 25 centigrammes of hydrochloride of quinine, can be given in doses of two per day—one in the morning, and the other in the evening—with a little water or other liquid.—*Chem. and Drug.*

Constipation in Infancy.

HOLT states that the normal stools in infancy usually contain 30 to 40 per cent. of fat; infant's food must contain much more fat than can be absorbed. If cream, containing 18 per cent. of fat, is substituted for a portion of the cow's milk, the stools usually become softer. Milk-sugar has little

or no effect in relieving constipation. KALM, of New York, considers that massage, although resorted to, is a valuable measure for the relief of constipation. It should be practised on an empty stomach, and should consist in small, circular movements made with the tips of the fingers along the course of the ascending, transverse, and descending colon. The conventional position at stool is often responsible for rectal constipation. YALE is not quite sure that the habitual use of enemata causes chronic constipation. STARR has used with much satisfaction a suppository containing extract of belladonna and purified oleum mixed with codon-liver.—*The Med. News.*

Treatment of Uremia.

RENAUT, in treating uræmia, endeavours to overcome the renal impermeability by the application to the loins of leeches, which he greatly prefers for this purpose to wet cupping. He demonstrated in 1888 the anastomoses which exist between the subcutaneous blood vessels of the loins and those of the cortex of the kidney. Inhalations of oxygen may be of use in aiding the blood to oxidise the retained toxic products. To increase the circulation in the kidney, the muscular substance of the heart must be stimulated, and for this purpose RENAUT prefers the administration every four days of 1 milligramme of crystallised digitalin, to be continued even after the renal obstruction has been removed. A milk diet, although it usually increases the daily amount of albumen secreted in the urine, is to be preferred on account of its diuretic action, and because it is a diet yielding very little toxic residue. During the uræmic attack subcutaneous injections of ether act as a cardiac stimulant, and to some extent render the nervous system insensible to the action of the toxic agents of uræmic origin.—*B. M. J.*

Pilocarpine in Alcoholism.

IN alcoholism, DOCTOR JOSHAM recommends one-third grain doses of pilocarpine hypodermatically, and declares "its sobering effects are remarkable; sleep ensues, and the patient wakes up a perfectly rational being. The tense, red, bloated countenance and bleared, congested eyes pass away, the features become calm and easy, the skin soft and clear.—*Proc. Med. Jour.*

Solvents for Quinine Sulphate.

CROUZEL considers sulphuric acid objectionable as a solvent for quinine sulphate on account of its disagreeable taste, its action on the mucous membrane, and its interference with the digestive fluids and ferments. He considers tartaric and citric acids free from these objections. For hypodermatic injections the best proportions for dissolving one gramme of quinine sulphate are: 20 centigrammes of tartaric acid or 40 centigrammes of citric acid, in 120 grammes of distilled water.—*Bulletin of Pharmacy.*

Correspondence.

"LUMBRICUS IN GRAVEL."

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I must apologise for the injustice I have done Dr. BRITTO in assuming he was humorously inclined. The levity of my letter must have sorely jarred upon his deep earnest convictions. I shall endeavour to look at the subject with all the reverence due to a new discovery.

Dr. BRITTO accuses me of that which he is really guilty i.e., of jumping at conclusions. He also states that I condemn without a trial. I retort, he advocates without "having had an opportunity of testing his supposition in any single case."

Let me examine for a moment the basis on which he propounds this new departure in practical therapeutics. On a memorable fishing excursion of loving memory an idea struck him. Unlike the venerable Archimides on a no less memorable bathing excursion, he cries "Eureka"; not on the spur of the moment, but after many years. In a word, looked at by the light of after-times, some unfortunate earthworms lay in a shell, imbedded in mud. A night passed over; and lo and behold! the mud had disappeared. Lumbricus had a dainty dinner and lay asleep wrapped in a mantle of mucus. This, bereft of the language in which it is dressed, is Dr. BRITTO's observation. How many a thoughtless school-boy disciple of amiable ISAAC WALTON has had a like experience! But the practical and useful lesson therefrom was left to Dr. BRITTO to unfold. He says "this led me to think that left, these worms possess properties, antilithic and dissolvent of gravel and urinary calculi."

Sir, I fail to understand the process of reasoning. The observation does not lead to any such conclusion, and experience does not confirm it. With admirable sang froid Dr. BRITTO foretells a brilliant future for his offspring, and views in fancy's mirror the leading scientists and chemists vying with each other for the honor of preparing the "Extractum Lumbricus Terrestis". It is immaterial to Dr. BRITTO in what form the worm is served for the therapeutical repast. He wisely leaves the onus of clinching his observations by experience, to other physicians, and is content to wait.

In an admirable article of a few issues back, you, Sir, deplored the tendency of young doctors to dabble in new and potent drugs to the exclusion of old and tried medicaments. I wish I had the ability to follow in the steps of Dr. NORMAN KERR and denounce in as forcible language the habit daily spreading to an alarming extent, of the use of those self-same new and potent drugs by the lay and ignorant public. Dr. BRITTO will excuse me if I frankly state my inability to test the efficacy of the treatment he advocates, till he places before the profession a more lengthy and a more logical exposition of his observations, deductions and his own practical experience, than is found in his first letter.

I do not wish to enter into any lengthy and heated controversy with my ancient friend, Dr. BRITTO. I claim your indulgence for this letter, and shall not trouble you further on the subject.

Yours &c., JOS. P. BARBOZA, M.B., C.M.
POLLIBETTA, SOUTH COORRI.

MR. BALM'S CASES OF OVARIOTOMY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have to make some remarks on the two clinical ovariectomy reports which were sent for publication to your valuable journal, and which appeared in the issue of the 1st of June.

I observe that the treatment and progress of the cases have been condensed by you, and in doing so a few mistakes appear, which I wish to rectify.

In case No. 2, writing of the description of the operation, you state "The peritoneum was then laid open and the cyst discovered to be adherent to it. The fluid was evacuated from the principal cyst, and it was then found that this cyst was also adherent." I alluded to one cyst only, i.e., the principal cyst. First on making the incisions, owing to tension due to the fluid, it was not conceivable how far the adhesions existed, but on emptying the principal cyst it was clear. As you put it, we understand that a daughter cyst was found to be adherent first and then the principal cyst—which is putting the cart before the horse.

In the treatment "At 5 P.M. the patient vomited and 10 grains of oxalate of cerium were given." I had a singular verb, for I took the powder in one mass. (!)

Again "She slept till 1 A.M. Four ounces of milk were administered at this hour." I had 4 oz. of milk was given her then. (!) As you omitted the dietetic treatment, you might as well have omitted this also. Moreover, the sentence sounds odd, and the giving of the milk "at this hour" implies as if this was a "*sine qua non*" line of treatment.

"An antimony and paregoric mixture was given" instead of were given.

"On the 10th she passed a round worm after the turpentine enema was administered, and thereafter progressed well." It was not the passing of the round worm that made the case to progress but the free action of the enema.

"One suture was removed on the 11th and two more the next day." You don't assign the reason why they were removed. Pus was seen in the wound and to give free vent to it I removed them.

Yours &c., E. M. BALM,
District Surgeon.

PARDHANI, 16th June 1895.

[All we have to say about this matter is that we cannot afford space for lengthy cases giving minute details of their progress: thus at 5 A.M. milk and medicine were given: at 8 A.M. something else, at noon something more, then again at 3 P.M., 5 P.M., 8 P.M. &c. &c. and so on for 10 to 15 days, page by page. As to the grammatical errors readers can judge for themselves.—Ed., I. M. E.]

:0:

THE MEDICAL PROFESSION AND PROPRIETARY MEDICINES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I read in your issue of the 18th March 1895, that the proprietary medicine trade would never have reached its present gigantic dimensions if medical men and medical journals refused to be gulled into granting commendatory certificates and notices of proprietary medicines. I quite agree with your correspondent, Mr. N. H.

Martin, but the difficulty is that when professional certificates are refused or not obtained, the proprietors get such certificates from non-professional men of respectability; and these, though not carrying any very considerable weight, are equally misleading. I have myself seen the patentee of a *sermo* (antimonial external application for the eyes) going with a sample packet to an Inspector of Schools and asking for a certificate which was, I believe, refused, but the man was successful in gaining his object from several other gentlemen. When refused a certificate, the man was seen to offer presents, e.g., a bag of crystallised sugar, &c. If the giving of extensive series of advertisements and presenting samples to the editors of medical journals are really the means of obtaining flattering notices of proprietary medicines without any reference to the efficacy of the latter, nothing need be said of non-medical journals, and nothing can be more misleading to the public at large.

Yours &c., JAIKISAN DAS, L.M. & S.,
Assistant Surgeon, Kulu, District Kangra.

THE EXTERNAL USE OF ACONITE ROOT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly give some space in your valuable journal to the following? The external use of aconite root has been found very useful by me in relieving pain and subsiding the swelling of the lymphatic glands, particularly those of the groins and axillæ. My mode of applying it is very simple. I get a root of aconite and rub it with a little water on some stone. When the water becomes turbid, I apply it on the swelling and advise the patient to use dry fomentation over it in addition. Many cases have been cured who came under my treatment before their buboes were ripe. I give details of one case which came under my treatment last month:—A young man by name Sukh Ram, was suffering from sympathetic buboes of both groins. On examining, I found them very much swollen and painful, I advised him to apply aconite root and dry fomentation over them. By this treatment he got some relief from pain on the first day and within a fortnight all the swelling subsided. The fomentation was carried out by means of a heated brick wrapped up in a piece of cloth. The native names for aconite root are: *Muthia telia*, *Telia bikh* or *bish*, and the hill men of this place call it *Mohra*.

Yours &c., THANA RAM,
Hospital Assistant.

SIMLA.

HOSPITAL ASSISTANTS' UNIFORM.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Can you let me know if Hospital Assistants are permitted to wear "M" on their shoulder straps and the black "tab" on their collars? In the Madras Presidency some wear only "M," others the twisted gold cord, and a third section wear both the M and the tab. I do not see any mention made of the above departmental badges in Appendix I, A.R.I. Vol. VI. I would also like to know what are the Regulation color and pattern of boots allowed to be worn by Hospital Assistants when in *khaki* dress, as the Regulations are silent on this point.

Yours &c., BROAD BRIM.

[We believe no one ought to go outside the regulations. Ammunition boots are always uniform.—Ed., I. M. R.]

W. M. O'S. COLORS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I would call your attention to the Editorial remarks *anent* a letter from me to yourself dated the 16th August 1893, in which matter up to date, as far as I am aware, no measure has been settled upon for general adoption.

Yours &c., A. BEALE,

Assistant Surgeon, R. I. M. S. Clive.

PORTSMOUTH, 24th May 1895.

REVIEWS.

PRACTICAL MANUAL OF DISEASES OF WOMEN AND UTERINE THERAPEUTICS *for students and practitioners.* By H. MACNAUGHTON-JONES, M.D., M.C.H., M.A.O. (Hon. Caus.), F.R.C.S.I. & E., Examiner in midwifery and diseases of women and children in the Royal University of Ireland, and Lecturer on Surgical and Descriptive Anatomy, Queen's College; Consulting Surgeon to the Maternity and to the Women and Children's Hospital, Cork, &c., &c. Sixth edition, revised and enlarged. London: BAILLIERE, TINDALL & COX, 20 and 21, King William Street, Strand. 1894. Illustrated. Pages 766. Price 12s 6d.

This most notable work on gynecology by such a mature and experienced writer as Dr. MACNAUGHTON-JONES needs but little of the *labor limæ* to render it perfect. A work that has reached its sixth edition needs no critic to handle it. It speaks for itself. All we can do, therefore, is to point out the many excellent addenda made in the present edition and compare it generally with the one immediately preceding it.

The work has gone through the six editions in the comparatively short period of 10 years, and during this time such rapid strides have been made in the clinical, pathological and operative departments of GYNECOLOGY that frequent alterations had to be made in the previous editions, while the present one has had to be re-written, re-arranged and re-illustrated. Considerable additions have been made also, in the pathological and surgical portions; new chapters having been added on *Uterine reflexes*, *Sutures and ligatures*, *The Surgical treatment of uterine fibromata*, *Affections of the Fallopian tubes*, *Tubal pregnancy*, and *Ovarian affections*. To make room for these additions, the chapters on Diseases of the Mammary Gland have been omitted, as also certain minor topics. The book still maintains its usual small bulk. Names of authorities quoted, are fully acknowledged and appended in list form. The illustrations are numerous, well-executed and explain the text admirably. A number of them appear in this new edition for the first time.

As a work intended for students and practitioners, Dr. MACNAUGHTON-JONES's Manual of Diseases of Women and Uterine Therapeutics has been written in a thoroughly concise and practical manner, presenting the latest advances in gynecology and the most recent researches in therapeutics thereanent. Dr. MACNAUGHTON-JONES has to be congratulated upon the marked success that has attended the publication of his work. It will, no doubt, prove as popular as, (if not more so than), the editions which have preceded it. The moderate price for such a complete

fitly, handy compendium will place it within the reach of all. The printing, binding, paper and finish of this volume are of the highest order.

THE BOOK OF PRESCRIPTIONS: containing *apocrypha* of 3,000 prescriptions, collected from the practice of the most eminent physicians and surgeons, English and Foreign. Comprising also a compendious history of the materia medica, lists of the doses of all official or established preparations, and an index of diseases and remedies. By **HENRY BEASLEY**. Seventh Edition. London: J. and A. CHURCHILL, 11, New Burlington Street. 1892. Pages 599. Price 7s. 6d.

This well-known and extensively read little formulary of pharmacology is now in its seventh edition. This fact coupled with the wide reputation enjoyed by "Beasley's Prescriptions," amply justify the inception of another edition. Many alterations and additions are made in the present edition—e.g., the nomenclature of certain substances has been changed to suit the scientific terms in vogue at the present day. For instance, names of drugs ending in *a*, are now altered to *ii*; such as *sodæ bicarb.* into *sodii bicarb.*, *potassæ bicarb.* into *potassii bicarb.*, &c. The alkaloïds now terminate in "*ina*" in Latin, and "*ins*" in English—as *strychnina*, *strychnine*; *quinina*, *quinine*, &c. In writing prescriptions of *fluid* drugs, \mathfrak{ss} and \mathfrak{ij} are now altered to simply the $\frac{1}{2}$ (ounce) and $\frac{1}{4}$ (drachm). We need not dwell at any length on the virtues and excellences of the little compendium before us. The fact of its extensive utilization speaks more eloquently than could the reviewer's pen as to its usefulness, and the compact, terse, complete nature of its contents. As the busy physician's *vade mecum* and a book of handy and ready reference in times of difficulty, it would not be easy to find its equal.

The little volume opens with a list of the signs and abbreviations used in prescribing, and a list of Latin words and phrases, which is very complete and helpful. Then follow the drugs, in alphabetical order, each drug is shortly described, giving its properties, solubility, dose and uses, after which a number of prescriptions follow from some of the most eminent physicians and surgeons illustrative of the various modes of exhibiting the medication in question, the ailment for which it is prescribed being added in italics; lastly there is appended an index of diseases with appropriate remedies prescribed for each.

The little treatise may well be styled, "The Physician's friend." We can most heartily commend its being adopted as a daily companion.

CATALOGUE OF SURGICAL INSTRUMENTS AND APPLIANCES: manufactured by **Messrs. ARNOLD AND SONS**, 81 West Smithfield, and 1, 2, & 3, Giltspur Street, London, E. C. 1895. Pages 818.

We have before us, beautifully bound in cloth boards, the latest issue of **Messrs. ARNOLD & SONS'** excellent catalogue of Surgical Instruments and Appliances. The very name of **ARNOLD** on a Surgical implement is a guarantee of *first class* quality, and English manufacture. This firm is a very old established one, having been founded in 1819, and is a very *versatile* for all kinds of surgical require-

ments. The catalogue is a most comprehensive and complete one, consisting of 818 pages, and is probably most exquisitely illustrated with woodcuts. A copious index, in alphabetical order, prefaces the work.

Messrs. ARNOLD & SONS are always ready to adopt any suggested improvements in instruments, or carry out original ideas. They employ only the most experienced **ENGLISH** workmen, and the very best material in their factory and can thus guarantee every article manufactured by them, which is thoroughly tested and examined before being sold. Their Orthopedic appliances are especially good and well-finished, and combine strength with lightness—a great desideratum. Their manufacture of Artificial Limbs has also received especial attention and care. Considering the superior quality of goods turned out by them, **Messrs. ARNOLD & SONS'** prices cannot be regarded other than moderate.

We have, however, in the present review, to do more with their catalogue than the *Firm per se*. The possession of such a well-printed and well-illustrated volume is in itself a most useful acquisition, and must have cost the Firm and their collaborators much time and labour to produce such a first class price-list, in every way a worthy exponent and index of the prestige and good standing of **Messrs. ARNOLD & SONS'** Establishment, the *recherché* style of which, has already obtained a world-wide renown. We congratulate them on their past successes and honors, and trust that the large share of patronage enjoyed by them at present, may be increased a hundredfold.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Surgn. Lieut.-Col. D. P. MacDonald, M.D., Sen. Med. Offr., Port Blair, has obtained priv. leave for sixty-eight days from the 1st August.

The undermentioned Surgn.-Lieuts. apptd. to Bombay Estab. reported their arrival at Bombay on dates specified:—Samuel Evans, 21st April; James Haldane MacDonald, 6th April.

Surgn.-Col. James Cleghorn, M.D., to be Surgn. Maj.-Genl., 29th March.

Brig.-Surgn. Lieut.-Col. John Henry Newman, M.D., to be Surgn.-Col., 29th March.

Brig.-Surgn. Lieut.-Col. James Charles Gordon Carmichael, M.D., to be Surgn.-Col., 29th March.

MADRAS SUBORDINATE MED. ESTAB.—Senr. Asst. Surgn., with honorary rank of Surgn.-Lieut., George Albert Waite, to be Senr. Asst. Surgn. with honorary rank of Surgn.-Capt., 12th Jan.; First class Asst. Surgn. Charles Robert Heneaud to be Senr. Asst. Surgn. with honorary rank of Surgn.-Lieut., 12th Jan.

The Queen has approved of the retirement from service of the undermentioned officers:—

BENG. MED. ESTAB.—Surgn. Maj.-Genl. William Roche Bice, M.D., C.B., 29th March; Brig.-Surgn. Lieut.-Col. Archibald Cameron, M.D., 1st April.

MADRAS MED. ESTAB.—Brig.-Surgn. Lieut.-Col. James Smith, 1st April; Surgn.-Maj. Donald Bleum, M.D., 10th March.

Surgn.-Majs. Arthur Henry Coles Dane, M.D., John Philip Greany, M.D., George Edward Elton Burroughs James McCloghry to be Surgn. Lieut.-Cols. after completing 20 years' full pay service from 31st March.

Surgn.-Capt. Mackintosh Alexander Thomas Oddie, M.D., and William Henry Quicke to be Surgn.-Majs. after completing 12 years full pay service, 31st March.

Surgn.-Maj. S. J. Thomson, I. M. S. (Beng.), Depy. Sany. Commr., is apptd. to be Sany. Commr., N.-W. P. and

Order with effect from date on which he assumed charge of office as Brig.-Surgn. Lieut.-Col. G. Hetchum, M.D.

Samuel Neville Ellis and Francis John Sullivan, after passing final exam., are admitted into service as 3rd class Asst. Surgns. from 6th June.

Surgn. Lieut.-Col. to be Brig.-Surgn. Lieut.-Col.—Christopher William Oakthrop, M.D., vice Brig.-Surgn. Lieut.-Col. J. H. Newman promoted.

William Alexander Crawford Roe, *vice* Brig.-Surgn. Lieut.-Col. J. C. G. Carmichael, M.D., promoted.

SUR. MED. ESTABL.—First class Asst. Surgn. James Kelly to be Senior Asst. Surgn. with hony. rank of Surgn.-Lieut.

Second class Asst. Surgn. Cecil George Stanley Jenkins to be 1st class Asst. Surgn.

Third class Asst. Surgn. Charles Horace Wachsel to be 2nd class Asst. Surg. from 2nd Jan., *vice* Senior Asst. Surgn. and Hony. Surgn. Lieut. C. Atkins, deceased.

Third class Asst. Surgn. William John Gillson to be second class Asst. Surgn. from 14th Jan., *vice* 2nd class Asst. Surgn. C. E. H. Cornelius, deceased.

Third class Asst. Surgn. Joseph Seymour Herring to be 2nd class Asst. Surgn. from 19th April, *vice* 2nd class Asst. Surgn. G. D. Coleman, dismissed.

Third grade Asst. Surgn. Harman Doss, having passed prescribed exam., is promoted to 2nd grade from 6th May.

BENGAL GOVERNMENT.

Asst. Surgn. Umes Chunder Banerjee is allowed leave for six months.

Surgn.-Maj. Dharmadas Basu reported his departure from India, on furlough, on 2nd May.

Mily. Asst. Surgn. A. E. DuBois held sub. *pro tem.* appt. of med. offr. at Sandheads from 20th March to 11th April.

Asst. Surgn. Nobin Chunder Dutt, of Sadar Dispy., at Darbhanga, held med. charge of civil station of Darbhanga, in addition to his own duties, from 25th to 28th March and from 5th to 17th April.

Asst. Surgn. Preembar Mitter is apptd. to do superny. duty at Med. Coll. Hosp.

Asst. Surgn. Khirde Chandra Chowdhuri is apptd. to do superny. duty at Med. Coll. Hosp.

Asst. Surgn. Chuni Lal Nandi, a superny. at the Presdy., is apptd. to have tempy. med. charge of Hutwa Raj Dispy. in Baran Dist. during absence of Asst. Surgn. Ramana Krishna De, on tour with Maharaja.

Asst. Surgn. Akshoy Kumar Nandi, a superny. at Med. Coll. Hosp., is apptd. on probation as an additional Asst. Surgn. in Chemical Examiner's Dept.

The services of Surgn.-Maj. E. F. H. Dobson, M.B., I.M.S., (Beng.) are replaced at disposal of Chief Commr. of Assam, from date on which he was relieved of his duties as Offg. Protector of Emigrants and Supdt. of Emigration, Calcutta.

Mily. Asst. Surgn. W. A. Williams, civil Med. Offr., Balasore, is apptd. to be civil Med. Offr. of Jalpaiguri, *vice* Dr. J. L. Hendley transferred.

Dr. J. L. Hendley, civil Med. Offr. Jalpaiguri, is apptd. to be Civil Med. Offr. of Balasore, *vice* Mily. Asst. Surgn. W. A. Williams, transferred.

Having passed the prescribed Exam. 2nd grade Asst. Surgn. Khirde Chunder Roy is promoted to 1st grade from 1st May.

Asst. Surgn. Satyabari Chatterjee is allowed leave for six months.

First class Asst. Surgn. James Kelly to be Senr. Asst. Surgn. with honorary rank of Surgn.-Lieut. from the 2nd Jan. 1895, *vice* Senr. Asst. Surgn. and Hony. Surgn. Lieut. C. Atkins, deceased.

PUNJAB GOVERNMENT.

Second class Hosp. Asst. Saadat Ali, from Syndwala to Kamalia Dispy., Montgomery Dist., which he joined on 18th May, relieving 1st class Hosp. Asst. Sahadat Ali.

First class Hosp. Asst. Sahadat Ali, from Kamalia to Syndwala Dispy., Montgomery Dist., which he joined on 24th May.

First class Hosp. Asst. Basm Chand, Rawalpindi City Branch Dispy., was deputed to charge of Masro Dispy., Rawalpindi Dist., from 3rd to 11th May, during absence of Asst. Surgn. Harman Das at Lahore to attend Septennial Exam. of Asst. Surgns.

Third class Hosp. Asst. Goverdhan Das, Civil Hosp., Rawalpindi was deputed to Nurpur Fair to Rawalpindi Dist., from 4th May to 18th May, when he reverted to Rawalpindi Civil Hosp.

On being recalled from priv. leave granted to him in Punjab Gazette, Med. Dept., 1st class Hosp. Asst. Badrud-din resumed charge of Pakpattan Dispy., Montgomery Dist., on 21st May.

Third class Hosp. Asst. Khair-ul-din, Pokoe Hosp., Dera Ghazi Khan, has obtained three months' priv. leave, and was relieved of his duties on 20th May by 3rd class Hosp. Asst. Tufel Ram, Jail Hosp., Dera Ghazi Khan, who held charge in addn. to his other duties.

The extraordinary leave without allowances granted to Asst. Surgn. B. C. Ghosh in Punjab Gazette Med. Dept. is extended by 13 months.

Asst. Surgn. Daulat Ram, doing genl. duty at Jullundur, was deputed to Bhadarkali Fair at Niaz Beg, Lahore Dist., from 18th to 21st May. He rejoined Jullundur Civil Hosp. for genl. duty on 22nd May.

On termination of priv. leave granted to him in Punjab Gazette Med. Dept., Asst. Surgn. Kali Nath Mai was apptd. to do genl. duty at Mayo Hosp., Lahore, from 11th May.

On return from priv. leave granted to him in Punjab Gazette Med. Dept., Asst. Surgn. Krishna Chandra resumed charge of Gujrat Dispy. on 20th May, relieving Asst. Surgn. Sohin Karm Singh.

First class Hosp. Asst. Ghulam Rasul, from Mardan Dispy., Peshawar Dist., to Rahon Dispy., Jullundur Dist., which he joined on 12th May, relieving 1st class Hosp. Asst. Kifayat Ulla Khan.

First class Hosp. Asst. Kifayat Ulla Khan, from Rahon Dispy., Jullundur Dist., to Phillour Police School Hosp., Jullundur Dist., which he joined on 14th May, relieving 1st class Hosp. Asst. Bishan Das.

Third class Hosp. Asst. Nathe Khan, from Indri to Arnault Dispy., Karnal Dist. which he joined on 17th May, relieving 1st class Hosp. Asst. Abdul Rahim.

First class Hosp. Asst. Abdul Rahim, from Arnault to Indri Dispy., Karnal Dist., which he joined on 22nd May.

First class Hosp. Asst. Mohsan Ali, at present attached to Ballabgarh Dispy., Delhi Dist., having passed English Qualification Exam. is entitled to higher rate of pay of his grade, from 17th April.

Surgn.-Maj. M. O'Dwyer, Civil Surgn. Jullundur, has obtained furlough on (m. c.) in India for three months, from 26th May.

Asst. Surgn. Sobha Ram, in charge of Jullundur Civil Hosp., is apptd. to offc. as Civil Surgn. of that station, in addn. to his own duties, from 26th May, *vice* Surgn.-Maj. M. O'Dwyer, proceeding on leave.

Local student Jowahir Singh having passed final exam. of Lahore Med. School, is admitted into service of Govt. as a 3rd class Hosp. Asst. from 10th May, and apptd. to do genl. duty at Mayo Hosp., Lahore.

The leave granted to Asst. Surgn. Girdhari Lal in Punjab Gazette Med. Dept. is extended by seven days.

On return from priv. leave granted to him in Punjab Gazette, Med. Dept., 3rd class Hosp. Asst. Ganga Bishen resumed charge of his duties on Chenab Canal, Gujranwala Dist., on 22nd May.

First class Hosp. Asst. Pir Bakhsh, Bannu Dispy. and Bannu Jail and Police Hosp. has obtained one year's leave (m. c.) and was relieved of his duties on 31st May by Asst. Surgn. Parshotam Das, Imperial List, transferred from Mooltan.

The following exchange of appts. was made in Dera Ismail Khan Dist. in interests of public service:—

Second class Hosp. Asst. Nawab Khan, from Gomal Pass to Kulachi Dispy., which he joined on 19th May.

-3rd class Hosp. Asst. Dasanul Khan, from Kulachi to Gomai Pasa Dispy., which he joined on 17th May.

Second class Hosp. Asst. Suchet Singh, doing genl. duty at Gujarat, to N.W. Railway, Amritsar, which he joined on 31st May, relieving 1st class Hosp. Asst. Abdul Rahman, granted one month's priv. leave.

On return from priv. leave granted to him in Punjab Gazette, Med. Dept., dated 26th March, 3rd class Hosp. Asst. Sheikh Ahmad was apptd. to do genl. duty at Rawalpindi on 19th May.

Third class Hosp. Asst. Sheikh Ahmad, from Rawalpindi to Gogranwala for genl. duty from 31st May.

Asst. Surgn. Sodhi Karm Singh, doing genl. duty at Gujarat, to Civil Hosp. Amritsar, from 31st May, relieving Asst. Surgn. Mehr Chand II, Rai Bahadur.

Asst. Surgn. Har Narain, from Lahore Central Jail to civil Hosp., Delhi, for genl. duty, from 29th May.

Third class Hosp. Asst. Lohoria Ram, from Pakpattan Dispy., Montgomery Dist., to Sheikh Budin Dispy., Dera Ismail Khan Dist., which he joined on 27th May.

Second class Hosp. Asst. Umar Chand, at present in charge of Miani Dispy., Shahpur Dist., having passed English Qualification Exam, according to test laid down in G. G. O., is entitled to higher rate of pay of his grade from 17th April.

Asst. Surgn. J. D. Rebelro, doing genl. duty at Lahore, is apptd. to med. charge of Sheikh Budin from 18th May.

Senior Asst. Surgn. J. Barker is transferred from Hissar to Rohtak Dist. as Civil Surgn., and assumed charge of his duties on 3rd June, relieving Asst. Surgn. Fattah Chand, M.B.

Asst. Surgn. Fattah Chand, M.B., Offg. Civil Surgn., is transferred from Rohtak to Hissar, where he assumed charge of his duties on 3rd June.

Asst. Surgn. Ramji Lal, Hissar Dispy., held charge of civil med. duties of Hissar Dist., in addn. to his own duties, from 31st June.

MADRAS GOVERNMENT.

Surgn.-Maj. Sarkies Carrapiet Sarkies to act as Surgn. third dist., Madras, during absence of Bridge-Surgn. Lieut.-Col. H. J. Hazlett.

Surgn.-Capt. William Molesworth, M.B., to act as additional med. offr., Genl. Hosp., Madras, during employment of Surgn. Capt. R. Robertson, M.B., on other duty.

Surgn.-Maj. John Smyth, M.D., to act as Fort Surgn. with Port and Marine duties, during absence of Surgn. Lieut.-Col. H. Allison, M.D., on leave.

Surgn.-Capt. Gerald Godfray Giffard to act as Resid. Med. Offr., Genl. Hosp., during employment of Surgn.-Maj. J. Smyth, M.D., on other duty.

The services of the undermentioned officers of Indian Med. Service (Madras), are placed temply at disposal of Govt. of Madras:—Surgn.-Capt. W. Molesworth; Surgn.-Capt. C. Donovan.

BOMBAY GOVERNMENT.

Asst. Surgn. Nilkant Dayabhai, L.M. & S., is allowed leave (m. c.) for one year from 22nd March.

Surgn.-Capt. John Blackburn Smith and Asst. Surgn. Mancherji Jamsaji Mistri respectively delivered over and received charge of Shikarpur Prison on 28th May.

Surgn.-Maj. R. J. Baker, M.D., I. M. S. (Bom.), Resdy. Surgn. and ex-officio Asst. to Political Resdy. in Turkish Arabia, is apptd. to offce. as Med. Offr. of 2nd Regiment, Central India Horse, and of Western Malwa Political Agency from 3rd May, and during absence on leave of Surgn.-Capt. C. M. Moore.

CENTRAL PROVINCES GOVERNMENT.

Second class Civil Hosp. Asst. Ujagar Parshad, doing duty under orders of Civil Surgn., Wardha, is apptd. to Jail and Police Hosp., Wardha.

On being relieved by Civil Hosp. Asst. Ujagar Parshad, 3rd class Civil Hosp. Asst. Balwant Laxman, attached to Jail and Police Hosp., Wardha, is directed to do duty under orders of Civil Surgn., Nagpur.

Third class Civil Hosp. Asst. Waman Daji, doing duty under orders of Civil Surgn., Nagpur, is directed to do duty under orders of Civil Surgn., Bhandara.

Third class Civil Hosp. Asst. Raghunath Panchal, doing duty under orders of Civil Surgn., Jabalpur, is directed to do duty under the orders of Civil Surgn., Saugor.

Third class Civil Hosp. Asst. Ramkrishna Patilaji, doing duty under orders of Civil Surgn., Nagpur, is posted to Jail Hosp., Sambalpur.

On being relieved by Civil Hosp. Asst. Ramkrishna Patilaji, 3rd class Civil Hosp. Asst. Govind Deo Rao, attached to Jail Hosp., Sambalpur, is posted to Police Hosp., Raipur.

Brig.-Surgn. Lieut.-Col. John Henry Newman, M.D., to be Surgn.-Col. from 29th March.

First class Civil Hosp. Asst. Anwar Ali, doing duty under orders of Civil Surgn., Nagpur, is granted twenty-one days' priv. leave from date he may be permitted to avail himself of it.

On expiry of three months' priv. leave granted to him, 3rd class Civil Hosp. Asst. Bhagirath Parshad is directed to do duty under orders of Civil Surgn., Nagpur.

N.-W. P. AND OUDH GOVERNMENT.

Surgn.-Lieut. W. Young, M.B., C.M., I. M. S., (Beng.), to offce. as Supdt., Central Prison, Bareilly.

Surgn.-Capt. H. E. Drake-Brockman, Civil Surgn., 2nd class, whose services have been replaced at disposal of this Govt. by Govt. of India, Home Dept., to Muttra Dist.

Surgn.-Maj. E. S. Brander, Civil Surgn., from Muttra to Sitapur.

Surgn.-Maj. C. C. Vaid, Civil Surgn., from Sitapur to Haridol.

Mily. Asst. Surgn. E. P. Clement, Offg. Civil Surgn., from Haridol to Oral.

Surgn.-Capt. D. W. Scotland, Offg. Civil Surgn., from Oral to Azamgarh.

The following 3rd grade Asst. Surgns. of Provincial Staff of N.-W. P. and Oudh, having successfully passed septennial professional exam., are promoted to 2nd grade from 1st May:—

Lalta Prasad, Rajendra Nath Chaudhri, Ranjit Singh Sarin.

The services of Surgn.-Capt. H. E. Drake-Brockman, Civil Surgn., Muttra, are placed temply at disposal of Govt. of India, Foreign Dept.

BURMA GOVERNMENT.

First grade Hosp. Asst. Shaik Haldiat Ali, proceeding on three months' priv. leave, relinquished charge of Civil Hosp., Toungoo, on 21st May.

First grade Hosp. Asst. Nurruddeen relinquished, as an addnl. duty, charge of Civil Dispy., Letpadan, Tharrawaddy Dist., on 26th May.

First grade Hosp. Asst. Gobardhan relinquished charge of Ry. Dispy., Dabein, Pegu Dist., on 23rd May and assumed charge of Ry. Dispy. Myittha, Kyaukse dist. on 27th May.

Second grade Hosp. Asst. P. Thoymonsawamp Pillay, on transfer to Shwedaung, Promé Dist., relinquished charge of Jail Hosp., Thayetmyo, on 26th May.

Third grade Hosp. Asst. Raj Chander Barma is granted and extension of leave (M. C.) of eight days.

Third grade Hosp. Asst. Raj Chander Barma, on return from leave (M. C.) assumed charge at Jail Hosp. Thayetmyo, on 26th May.

Third grade Hosp. Asst. Anath Pundu Mukerji, on return from priv. leave, assumed charge of Civil Dispy. Letpadan, Tharrawaddy Dist., on 26th May.

Third grade Hosp. Asst. Shaik Hosan relinquished, as an additional duty, charge of Ry. Dispy., Myittha, Kyaukse Dist., on 27th May.

Third grade Hosp. Asst. Shaik Abdul Rahman, on availing himself of leave without allowance, for one year, relinquished charge of Jail Hosp., Moulmein, on 31st May.

Third grade Hosp. Asst. Chandra Shekora Roy relinquished charge of Police Hosp., Katha, on 22nd May and assumed charge of Jail Hosp. Moulmein, on 31st May.

Second grade Hosp. Asst. Sher Mahomed, on retransfer to Mily. Dept., relinquished charge of Civil Dispy., Shwedaung, Promé Dist., on 31st May.

Second grade Hosp. Asst. P. Thoymonewany Pillay assumed charge of Civil Disp., Shwagun, Prome Dist., on 31st May.

Second grade Hosp. Asst. P. Thoymonewany Pillay assumed, as an additional charge, duties of Supdt. of Sand Operations, Shwagun, Prome Dist., on 31st May, vice 2nd grade Hosp. Asst. Shat Mahomed.

Third grade Hosp. Asst. Abdool Wahid relinquished charge of Outpost Hosp., Nanyaseik, Mogaung sub-divn., on 15th May and assumed charge of Outpost Hosp. Pinka, Mogaung sub-divn., on 18th May.

Third grade Hosp. Asst. U. C. Chackerbutty relinquished charge of Outpost Hosp., Shwagu, Bhamo Dist., on 8th May, and assumed charge of Police Hosp., Bhamo, on 9th May.

Third grade Hosp. Asst. U. C. Chackerbutty relinquished charge of Police Hosp., Bhamo, on 17th May and assumed charge of Outpost Hosp., Shwagu, Bhamo Dist., on 18th May.

Third grade Hosp. Asst. Poromannand Mohapatra relinquished charge of Outpost Hosp., Paungbyin, Upper Chindwin Dist., on 24th May, and assumed charge of Police Hosp., Kindat, Upper Chindwin Dist., on 25th May.

Third grade Hosp. Asst. Tijmul Hussain relinquished charge of Police Hosp., Catha, on 21st May, and assumed charge of Outpost Hosp., Mohnyin, Katha Dist., on 26th May.

Third grade Hosp. Asst. Shaik Abdul Majid, on transfer to Kindat, Upper Chindwin Dist., relinquished charge of Civil Disp., Mahlaing, Mefkila Dist., on 30th May.

Surgn.-Capt. A. R. P. Russell made over, and Surgn.-Capt. C. N. Bensley, M.B., assumed, executive and med. charge of Rangoon Central Jail on 5th June.

G. O. C. C.

Surgn.-Col. W. T. Martin, M.D., leave (M. C.) for six months.

Surgn.-Col. A. Stephen, M.B., Offg. Prinl. Med. Offr., Assam Dist., is confirmed in that appt.

Surgn.-Col. J. C. G. Carmichael, M.D., Offg. Prinl. Med. Offr., Presdy Dist., is confirmed in that appt. from 2nd May.

ASSAM GOVERNMENT.

The services of 1st grade Hosp. Asst. Karam Ali Hazarika are dispensed with from 23rd May.

Third grade Hosp. Asst. Mahim Chandra Datta, a superny. in Goalpara Dist., is apptd. to med. charge of Rupsi Disp. in that Dist. from 27th May.

Asst. Surgn. Atul Chandra Rai, in med. charge of Coolie Depot at Tezpur, is apptd. temply. to hold civil med. charge of Nowgong Dist. during absence, on priv. leave, of Hony. Surgn.-Capt. J. McNaught.

Babu Baikuntha Chandra Purkayastha, a passed student of Dacca School of Medicine, is apptd. on probation for six months, as Civil Hosp. Asst. in Assam, and is posted to Gauhati for duty as a superny. from 5th June.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Re. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

ELKINS.—On 13th June, at Parel, the wife of Asst. Surgn. A. H. Elkins, of a son.

FORSYTH.—On 8th June, at 4, Elysium Row, Calcutta, the wife of W. Forsyth, F.R.C.S.E., of a daughter.

PRICE.—On the 5th instant, at Bungagora, the wife of J. Dods Price, District Medical Officer, Nowgong, Assam, of a son.

MARRIAGE.

MACNAB—DIXON.—On the 20th June, at St. Saviour's, Thandesi, Hazara, Surgn. Capt. Allan J. Macnab, I.M.S., Q. O. Corps of Guides, to Honoria, eldest daughter of Lieutenant-Colonel L. Deering, D.S.O., Commanding 36th Panjab Infy.

DEATH.

CASSIDY.—On 14th June, at Parnes, Coolin Park, Glasgow, son of Surgn.-Capt. and Mrs. C. Clemens Cassidy, aged four months.

NOTICES TO CORRESPONDENTS.

HINTS TO CONTRIBUTORS.

1. Write plainly and briefly and to the point. 2. Write on one side of the paper only. 3. Save postage by sending your papers by "Book Post," the wrapper having its sides open. 4. Every member of the Profession in India should do his little share in adding to the general stock of knowledge of tropical disease. 5. Write up interesting cases or a series of cases, give statistics bearing on the history, causation, prevention and treatment of disease. 6. Bear in mind that this Journal is a channel of communication between the members of our profession in the East; therefore send "Personal and General News items," and they will be recorded. 7. Write your views on socio-political topics, connected with the profession, official and non-official, in order to advance the interests of all sections of our calling. 8. Newspapers and journals sent for notice should have the parts intended for observation marked.

J. W. (Madras) "wishes to know if the Government gold medal, awarded to the best Hospital Assistant in the annual examination of the Madras Medical College, may be worn by its winners, and the color of ribbon that may be worn with it." College medals are not usually worn on the breast, nor would we suppose they could be worn on uniform.

Broad Brin says it is seven months since his war medal rolls were submitted, and that he has not yet received his medal.

J. K. D. (Sultanpore).—1. A Government Medical Officer is not entitled to any fee when called upon to give evidence in a Court of Law on behalf of the State. 2. He can claim all travelling and "out of pocket" expenses incurred. 3. For professional services rendered privately he is always entitled to his fees.

P. R. (Simla).—Your report is with us, and will soon be published.

A. K. C. (Gwalior).—We shall be glad to see you and to do all we can for you.

M. A. A. (Mon Asing).—Thanks for your paper, it will have early attention.

An enquirer.—There is no departmental difference made as regards promotions, &c., in the various grades of Assistant Surgeons, no matter what their qualification may be. Vacancies are filled by selection in the civil department.

C. F. P. (Melbourne).—The Medical Act of Victoria has been received, and we thank you for it. Your request with regard to your diploma will receive our best considerations. Join the Indian Medical Association without delay, particulars of which you will find in the Record.

C. A. T. (Tellicherry).—Your matter is dealt with in this number.

A. K. (Bharat).—Pill-pots with equal parts of tincture of belladonna and tincture of iodine, support the toothless, without any biting suspender and give quinine with rhubarb-pill morning and evening.

M. L. Larna (Lahore).—Same charge as Hospital Assistants.

S. W. C. K. (Bander).—Your reports are received, and will receive early attention.

K. G. S. P. (Kamjur).—Many thanks for your paper.

A. L. M. (Jalpaiguri).—Your cases have been received. Many thanks.

H. M. (Dishat).—Thanks for your paper.

A. V. M. K. (Bombay).—Your letter will appear in an early issue.

M. A. J. (Siara).—Later on.

Job.—Thanks for your letter.

Civil Apothecary (Madras).—The matter is under consideration. Have a little patience.

W. E. L. (Kyaukpyn).—Your case can be published without official reference.

Surgeon A. Beale, Portsmouth, and others.

DISPOSAL OF RUBBISH IN RANGOON.

THE labours of the Special Committee appointed as far back as 1893, to investigate this vexed question, have just been concluded. Of the four alternative schemes for disposal of town refuse, namely, destruction by incinerators, removal by rail, removal by water, and burial within Municipal limits, the last has been recommended as the cheapest. The Chief Commissioner, in reviewing the report, and impressed by the advice of one dissenting member, Surgeon-Colonel Baker, expresses regret that a permanent scheme was not arrived at. He also doubts whether any Member of the Committee can regard the scheme advocated in any other light than a temporary arrangement, and accepts it as such pending the proposal for a permanent scheme. It will now rest with the Committee, guided by their past experience, to decide on a final solution, pending the improvement of Municipal finances. The Chief Commissioner, as at present advised, thinks that the most satisfactory permanent method will be to remove the refuse out of town by rail, as rubbish depots in town must be limited. He considers it premature to decide against incinerators. Under the present scheme the rubbish from the western portion of the town will be buried at Ahlone, and that from the eastern portion near the slaughter-house.—*Indian Engineering.*

A PRECAUTION IN THE TREATMENT OF CONJUNCTIVITIS.

The surgeon should always exclude the possibility of GLAUCOMA (after careful examination), before instilling atropin in the eyes of any patient presenting symptoms of acute conjunctivitis, with chemosis, photophobia, &c. Without such precaution, the results would probably be disastrous.

The chief indication of the presence of Glaucoma is, of course, the extreme tension of the globes. Along with this there is the "steamy" condition of the cornea, which is often anæsthetic. The pupil is dilated and fixed. The patient complains of "foggy" vision and sees colored rings surrounding lights at a distance. There is also present a good deal of headache, nausea, vomiting, &c., which are often overlooked and ascribed to a "bilious attack." Hence in patients complaining of headache, vomiting, and rapidly diminished vision, the probability of GLAUCOMA should be suspected.

ORIGINAL ARTICLES.

SOME DIFFICULT CASES OF CHLOROFORM ADMINISTRATION.

BY ARTHUR NEVE, F.R.C.S. (Edin.)

Surgeon, Kashmir Mission Hospital, C.M.S.

THE fact that for all practical purposes ether is not available as an anæsthetic in India should enable the profession here to regard the chloroform controversy from an unbiased stand-point. Here it is not a matter of choice for ether cannot be kept; but it is not reasonable to declare that because chloroform is the only available general anæsthetic in India, therefore it is the best in a cool climate. Nor, if it could be proved that it is absolutely safe in this country, should we settle the controversy in that way. India could contribute two important facts, which perhaps may be elucidated. First, the relation of race to anæsthetics, and this might include the question of racial habits, such as vegetarian diet and abstinence from alcohol. Secondly, the effect of temperature and altitude upon chloroform anæsthesia. Can any clinical difference be established between the administration to natives of India of chloroform in hot weather with a mean temperature of over 85°F., or in cold weather with a mean temperature of 50° or lower at such stations as these temperatures exist, and does an altitude of 6,000 or 8,000 feet affect the question clinically? These practical contributions to debatable points might reasonably be speedily expected from Indian surgeons. A New Zealand surgeon claims that careful study of cases shews that the aborigines there are less liable to suffer from shock, and that Europeans, if insufficiently anæsthetised, are apt to die from inhibition of the action of the heart. Does Indian experience homologate this view? Could an Indian committee be formed to investigate all fatal cases occurring in this country? I published a case in the *Lancet* in which partial anæsthesia plus shock caused very serious symptoms. It referred to a strong Kashmiri, who required castration for sarcoma of a testicle. Owing to vomiting the anæsthetic was insufficiently administered; and at the moment of applying a clamp to the cord the patient became rigid, as in a tetanic spasm, and the heart's action stopped; the wound ceased to bleed. With difficulty—after inversion, injection of ammonia, and also per rectum of hot water, together with steady artificial respiration—the pulse began to flicker, the chest heaved, and the patient was restored. As he was sensitive to the knife. I then rapidly administered two drachms of chloroform, which the patient inhaled quietly, and the operation was finished deliberately and safely. I am convinced of the importance of this and similar cases. One which I narrated at the meeting of the British Medical Association at Bournemouth has the same lesson. A patient suffered both from severe heart disease and from stone in the bladder. Chloroform was timidly given, and as the staff was inserted, the patient gave a gasp and fainted. He was with difficulty restored to consciousness. A fortnight later I arrived in the town and was consulted. I offered to administer chloroform myself. Two drachms were given and the

operation was begun. As the patient had taken chloroform quietly, all seemed well, and I was asked to assist in the operation, leaving the house surgeon to continue the administration. Scarcely two minutes had passed before the reathing appeared to stop. What was the cause? An overdose? No, for no more chloroform had been added. It was the shock acting reflexly on a heart neither protected by consciousness nor by full anæsthesia. I append two cases of faulty administration that have occurred this year out of over 500 chloroformisations under my care. In both cases I was summoned from an adjoining room where I was operating. In one, a native assistant of considerable experience was operating, while another, who has chloroformed thousands of patients, gave the anæsthetic. When I entered, the patient had been partially inverted, the operator was performing artificial respiration, while the other drew out the tongue with the head back; but observing that the lips were purple, which was evidence of continued action of the heart, I at once put my finger down behind the tongue and raised the epiglottis. Immediately one heard the air rush into the chest, and in less than a minute a sighing inspiration shewed that natural respiration was recommencing. In this case I think an overdose had been given and the tongue had fallen back, and the traction upon it did not suffice to open a flaccid epiglottis. The other case was one in which chloroform had been badly taken, the patient struggling a little and afterwards incessantly spitting. Anæsthesia was pushed to stop this annoying reflex symptom, and the moment it ceased the respiration also stopped and the patient turned pallid. When called in, I lifted him on to the ground with his feet and body up and began artificial respiration; the air entered the chest, but for a few seconds the absolute pallor remained. Then there was a slow, natural inspiration; recovery was slow for a minute, and then, with a heave of the body, vomiting began, and the stomach emptied itself of two pounds of semi-digested rice. Here, as in other cases, the syncope was connected with a full stomach and was premonitory of the vomiting. There were two other cases very noteworthy. One was a woman with a gumma over the thyroid cartilage, with considerable dyspnoea, and a constant spasmodic cough. I administered chloroform myself, and began with a dose of ten minims on a towel. There was a moment of struggle, then she lay senseless, and the operation was begun. Her breathing was almost imperceptible and the pulse thready. No more chloroform was given, and the operation (which lasted about twenty minutes) was completed without a sign of consciousness, but soon afterwards she came slowly round. The other case was that of a lad with very great dyspnoea from the pressure of a goitre, which with each inspiration, was sucked down behind the sternum. As in the earlier case, only a few drops of chloroform were given, Mr. W. F. ADAMS kindly taking charge of its administration. I had well begun the operation when breathing stopped, and also the bleeding, except some venous oozing. No more chloroform was given. The legs were raised and artificial respiration began, &c. I went on with the operation and removed the portions of the goitre resting over the trachea. Still he remained unconscious, with great dyspnoea, owing to the flattened and infantile condition of the trachea, so I proceeded to open the trachea below the cricoid cartilage.

An ordinary tracheotomy tube gave no relief, so I inserted a gum elastic catheter for three inches down the trachea. Shortly after this the patient began to show symptoms of returning consciousness. In both these cases the blood was very venous, and the poisonous effect of the chloroform upon the medulla oblongata was at once manifested even in minute doses. There have been upwards of six thousand administrations of chloroform since 1875, without a single direct or indirect death, in the Kashmir Mission Hospital, though not a year passes without dangerous symptoms occurring in a few cases. We have seen (1) primary syncope from fear, and also from (2) laryngeal spasm; (3) secondary syncope from shock due to insufficient chloroform, and also from a proper dose acting on non-oxygenated nerve centres; (4) tertiary (sometimes secondary) syncope connected with vomiting; (5) apnoea from (a) mechanical causes, (b) spasm of the larynx, and (c) from the toxic action of an overdose (relative or absolute) on the nervous centres. In any of these ways life may be lost. The surgeon must hold clear views on the method of administration, so as to steer as clear as may be practicable in any given case of these various dangers; and he must be prompt to recognise the danger-signals of a dilated pupil, or gasping or stertorous breathing, or change of color in the lips. He must also be thorough as well as prompt in his method of restoration. If he have fewer accidents than his fellows, let him not attribute any special credit to himself, still less apportion blame to his neighbours, for the time may be near when he will himself meet with a fatal case due to idiosyncrasy of the patient.

THE HÆMATOZOON OF CHOLERA.

By SURGEON-CAPTAIN PATRICK HEHIA, M.D.,
F.R.S.E., F.R.C.S.E., D.P.H. (Cantab.)

Lecturer on Pathology and Clinical Medicine, His
Highness the Nizam's Medical School, Hyderabad.

IN the year 1892, I contributed to the *Indian Medical Gazette* an account of a series of special investigations on the discovery of a hæmatozoon in the blood of cholera patients. My paper was accorded the honor of being published as a special supplement to the issue of the 30th April of that year. That paper was in part reprinted in a number of periodicals, and various comments were issued on it. Some described it as a highly important discovery; whilst others expressed their incredulity. Some were generous enough to state that I had mistaken degenerated white blood cells for parasites of an amœboid character. Others again stated that the flagellate organisms described by me were elegant specimens of cotton fibre! These and several other similar remarks represent the greeting which that paper received. Considering that I had been 15 years at microscopical work, and that another paper on malaria, published shortly afterwards, contained a reference to control observations on healthy blood, it is needless to make any further remarks. On the welcome which my contribution to the pathology of cholera elicited since the publication of that paper, I have conducted two separate series of further observations, during extensive epidemics of cholera, but with that

greater attention to detail which further experience engenders, with the result that I have not been able to modify my original observations to any noteworthy extent, or in any essential particular—the main facts then observed have been verified repeatedly.

The present paper, however, proposes to deal with my later observations only, and on this occasion I would confine my remarks to the parasitic organisms met with in the blood, reserving a description of my observations on the dejecta for a later opportunity.

Before entering upon a description of this polymorphic sporozoon, however, I would refer to the general plan upon which the investigation was conducted, and the precautions that appear to be required, to make these observations successfully, and to some extent at least trustworthy. The following paragraphs give briefly, a description of the various phases of my hæmatozoon:—

(1). *Large spherical bodies*, some with granular, others with hyaline contents. They are sometimes surrounded with long ciliary processes of varying length and thickness, all of which move in one direction in a wave-like manner.

(2). *Small spheric cells*, of varying diameter, but usually about half the size of red blood corpuscles, having contents sometimes hyaline, sometimes granular, and possessed of from three to six well-defined ciliary processes growing at right angles from the surface of the body. These are, as a rule, found in considerable numbers, and their cilia are from 2 to 8 *micras* in length, and have a pinkish tinge. It is necessary, of course, to distinguish both these and the following from the blood-plates of Hayem.

(3). *Small amœboid bodies*, with one or two highly refractive spore-like structures in their interior. Whilst they are surrounded by loose soft protoplasm and furnished with from two to five thin flagellate processes, which, when seen with a bright light, have a pinkish tinge, move with considerable rapidity, and vary in length from 1 to 4 or 5 *micras*. These bodies are developed from various forms of large cells, from which they are set free in the process of disintegration. Frequently, however, they are motile, even whilst within the larger or parental forms, in which they gradually approach the border, and make their way into the surrounding fluid, appearing there as the small, free, moving amœboid structures just mentioned.

(4). *Ciliated spherical bodies*, of varying size, are always present in large numbers. In the dejecta they are seen to be developed from medium-sized cyst-like bodies. Sometimes these ciliated spherical bodies rupture and set free the contained embryonic bodies *en masse*, and, as a matter of fact, pressure on the cover-slip of the preparation frequently causes a number of the contained bodies to shoot out from the interior, rupturing the cell-wall in doing so. The various stages of the intra-corpuscular development of these bodies appears to be well brought out in stained preparations, especially when gentian-violet is used, considerable numbers of these ciliated spherical bodies are always present, no matter whether the observations be made early or late in the attack of cholera. In respect of their constancy, and of the part they play in the propagation of the various forms of this parasite, the

spheroidal bodies appear to me to be amongst the most important parasitic forms occurring in cholera blood. Although these bodies, in general, have a spheroidal form, they may rapidly develop into oval or ellipsoidal organisms. With regard to their size, they are usually larger than the red blood corpuscles from which they, in many cases, have made their exit. As we have elsewhere remarked, similar, if not identical, spheroidal bodies are developed independently of the red blood cells, from the more mature varieties of the parasite, and it is probable that the smaller varieties of the spherules, which are always present, are developed in the latter way only.

(5). *Cyst-like bodies* are always to be found. These bodies exhibit great diversity of form and character. A full description of the varieties would involve the writing of a more complete, comprehensive and pretentious paper than the present one.

(6). Various forms of *star-like organisms* are usually present in considerable numbers in all stages of the disease. They are sometimes very large, at other times small, intermediate sizes being by no means uncommon. They are extremely transparent, so much so, indeed, as to be invisible as corporate bodies during the active phase of their existence, appearing merely as bright, motile particles. The smaller varieties of these stellate bodies are structures described as "small ameboid bodies." This fact was made known by watching the ameboid bodies till they ceased to move. Much larger star-shaped organisms than those just mentioned are always to be seen. They consist of a central cell-like body, the shape of which varies as does also the size. A considerable number of flagellæ grow out from the surface, some of which are short, others long, some thick, others attenuated, but all the flagellæ appear to curve in one direction, each flagella usually assuming the form of the letter *f*. Occasionally the flagellæ of adjacent stars unite, forming a higher transparent reticular meshwork which must not, I need scarcely remark, be confounded with the similar but coarse meshwork formed by the fibrillæ of fibrin. Various forms of *flagellate organisms* are frequently to be found.

(8). In about 12 per cent of the slide-preparations of blood, long *flagellate organisms* may be seen. They vary in length from 15 to 40 *micras*, but have a tolerably uniform breadth.

(9). In about 6 per cent of cases these flagellæ may be seen to be encysted in a large oval or round cyst, in others they are seen to be just bursting through one extremity only being full. If the observations in connection with this body in cholera be continued, it will be observed that in these bodies disintegration begins at both extremities, and that, in common with the other parasitic forms, it eventually gives rise to a progeny of small spore-like organisms or ameboid bodies. Occasionally a number of flagellate bodies are seen clustered together, coiled round one another, or intertwined in various ways. In a small percentage of slide preparations of freshly-abstracted blood, one or more of these bodies may be seen in vigorous action.

It may be at once seen that the organisms above described differ in but few particulars from the parasite

of malarial fever, and this fact, to our reasoning, adds in no small degree, the great interest attaching to my discovery.

Should other observers bear out the statements herein made, we shall be justified in adopting generally, exactly the same preventive measures against cholera that we do against malarial infection, chief amongst which is the administration of quinine twice a day, morning and evening, in moderate doses. This we have done for the last four years, and we are not acquainted with a single instance in which it has failed to avert the disease, although we have passed through several epidemics. Believing that this organism has something to do with the production of many of the symptoms of cholera, we now treat all cases of that disease seen in the early stage, by the hypodermic injection of 10 grains of the neutral sulphate, giving 10 grains by mouth, and administering 30 grains by enema in the same way as we do in amebic dysentery. Up to date, we have scarcely had a sufficient number of cases to justify the expression of a conclusion on its merits.

The ease with which protozoa are killed as compared with bacteria, gives further interest to this observation.

The fact that in no case has it been definitely proved that the comma bacillus itself or its alkaloidal products either alone or conjointly by gaining access to the human body has produced cholera—a circumstance which goes much against its acceptance as the pathogenic agent of cholera.

Last year five students of Berlin drank the pure cultures with no effect except slight pyrexia in one case.

My first observation of the parasite was made under the following circumstances: I was making a series of blood examinations in all diseases of India; and I made my first examination of cholera blood on the 3rd June 1891, and after careful observation, I arrived at the startling conclusion that it contained the polymorphic forms of a parasitic sporozoa. There were several varieties present, and in considerable numbers, and several of the varieties were found moving about the field. I continued my observations for about 12 months after this, before publishing my first paper on the subject.

—:O:—

THE TREATMENT OF CHOLERA.*

By A. MITRA, L.B.C.P., L.R.C.S. (Edin.)

Chief Medical Officer, Kashmir.

HAVING had to deal with two most virulent epidemics of cholera in Kashmir during the years 1888 and 1892, I had ample opportunities to test most of the usual methods of treatment of that disease. I therefore now take this opportunity of relating to you the result of the treatment adopted by me and also of introducing for your discussion the subject of the therapeutics of cholera. At the very outset we are confronted with a disputed point. Supposing we are called to treat a case of cholera in the very first stage of the disease, soon after the patient has had one or two stools, shall we or shall we not try to arrest the discharges

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

from the alimentary canal, and to allay the irritation of it by the administration of astringents and opiates? If I am not mistaken, the practice in India is to exhibit astringents and opiates at this stage with a view to stop the discharges, and, by lessening the drain from the system, minimize the risks of the subsequent collapse. Side by side with my article on cholera in the *Medical Annual* (WRIGHT, Bristol) of the year 1892, there appeared a valuable contribution from the pen of that distinguished physician, SIR GEORGE JOHNSON, in which he deprecates the administration of opium in the first stage, and advocates an evacuant drug, such as castor oil, in order to get rid of morbid and pathogenic material. KOCH, he points out, failed to produce cholera in guinea-pigs until at the time he introduced the poison into the stomach, he injected a dose of tincture of opium into the peritoneal cavity, his object being to render it possible for the cholera bacillus to remain longer and gain a footing in the intestine. "Is it not obvious," SIR GEORGE JOHNSON argues, "that those who endeavour to arrest the discharges by opium are repeating upon the human subject the lethal experiments which KOCH and others have performed on guinea-pigs?" SIR GEORGE JOHNSON, however, says that a dose of opium may be given when the diarrhoea has continued for some hours, the stools being copious and liquid, and there is an absence of colic and abdominal distension. It is very curious to observe that this opinion of SIR GEORGE JOHNSON is an echo of that which we find expressed in the Hindu Treatise of medicine called *Nidan*. *Nidan* says:—"Do not attempt to arrest the evacuations in the first stage, that is in the stage of diarrhoea," but it advises a small dose of opium when the collapse commences.

Our modern experience in India is just the reverse. In the earliest stage of cholera, by stopping the evacuations, we often succeed in stopping the course of the disease, but when once signs of collapse set in, opium and its preparations do harm. As in a case of cholera, the treatment in the first stage is a most important one, and as in India during severe epidemics, the pills and mixtures, which have to be largely supplied for the treatment of scattered and remote populations, all contain opium, it is a matter of great concern to Indian medical practitioners to know which of the above procedures is ratified by science and supported by experience. No experiment can be made during the overwhelming pressure of a cholera epidemic, and it is therefore in time of peace that we should be fortified with the knowledge which is the most reliable weapon to fight with.

In the stage of collapse I believe everybody agrees that diffusible stimulants are the only remedial agents which help us to tide over the crisis of that stage. It has been seen that intravenous injection of hot saline fluid often produces good results, but such results are almost always temporary. During the reactionary stage the physician's resources are tried to the utmost and every particular case has to be judiciously treated according to its own merits. The epidemic of 1892 in Europe and America has brought before the profession several new methods of treatment. I have had fortunately no opportunity to test them, but I doubt not that some of you, here present, who have to deal with endemic cholera, may

be able to tell us the result of your experience of them. The principal of these methods are, as you are aware:—Centripetal arterial infusion, intravenous and intra-arterial injection of sterilized solution of common salt or hydrogen peroxide, hot air and hot water bath, opium subcutaneously before occurrence of collapse, subcutaneous injection of atropine, subcutaneous injection of anti-cholera, a metabolic product of bacteria like tuberculin, subcutaneous injection of oil of camphor as a stimulant, cocaine and chloroform, and irrigation of the stomach for vomiting, subcutaneous injection of hot saline solution in the algid stage in preference to intravenous injection, saline injection into the bladder, injection of carbonic acid into the stomach and intestines, diluted lactic acid, copious draughts of per-iodate solution internally and transfused under the skin, rectal injection of tannin or caustic, entero-clytic treatment, washing the stomach and bowels with solution of hydrochloric acid.

During the epidemic in Kashmir in 1892, the treatment adopted by me was as follows:—

If a case was seen early, that is to say soon after the purging or vomiting or both appeared, and if, as it often happens, signs of collapse were not present from the beginning, an astringent mixture with opium was administered every two hours for two or three doses. In such cases in which, on account of persistent vomiting, mixtures are not retained, morphine hypodermically, or opium and tannin entero-clytically, were administered. Two ready-made mixtures were largely used. Mixture No. 1 contained dilute sulphuric acid, tincture of opium, carbolic acid, and creosote, and mixture No. 2 was made up with acetic acid, spirits of nitric ether, camphor and ammonia aromatic. In the first stage mixture No. 1 was administered; a large mustard plaster was applied over the epigastrium, hot water bottles and friction or hot water bath were employed to relieve cramps. Acidulated water or mint and camomile tea was given to quench thirst. In the collapse stage, opium and its preparations were strictly forbidden, and mixture No. 2 was largely used. During reaction, if the temperature rose, the bath was used; if the liver was inactive, small doses of calomel were given. To stimulate the kidneys, tincture of cantharides was given internally with local counter-irritation. In cases in which there were signs of renal congestion or nephritis, cantharides was not used. Pilocarpine hypodermically acted very well in a few cases. To relieve cerebral congestion a few leeches applied behind the ear often produced a satisfactory result. Eighty cases were treated by me at the cholera hospital in Srinagar strictly according to the above method, 40 were cured and 40 died, shewing a death-rate of 50 per cent.

Fifty cases were treated with salol, 22 recovered and 28 died, showing a death-rate of 56 per cent.

The effect of LORBER's cure for cholera, of which some of you may have heard, was carefully watched in 50 cases; in 34 cases the medicine was commenced in the early stage, 14 recovered, 20 died, death-rate 58.8 per cent. In the remaining 16 the medicine was given during the collapse stage, 5 recovered, 11 died, death-rate 68.7 per cent. In the cholera hospital a special ward was allotted for a few

days for the treatment of cases by water only. Twenty-nine cases were treated with nothing but water from beginning to end; copious drinks of sterilized water were allowed; 15 recovered, 14 died, shewing a death-rate of 48.8 per cent. So you see I have not killed many by withholding drugs! This fact, I am afraid, will not be very palatable to our professional brethren of the *similibus curantur* principle.

Hypodermic injections of morphia and atropia, combined with sulphuric and carbolic acids internally, failed to yield any satisfactory result.

No improvement followed in the treatment of 4 cases by argenti-nitras internally and by enema.

In 3 cases cannabis Indica was tried. One made a rapid recovery and two died. In the collapse stage of 5 cases, gum ammoniac internally, together with stimulants and injection of sulphuric ether, was tried, but no effect was produced. No appreciable result was observed after blistering the yagus. Besides the above, chlorodyne, lead and opium pills, patent pills such as Cotter's, Daji's and Bellow's almalaj, were also used. At the end of the epidemic we found that out of a total of 16,845 cases to whom some sort or other of medical aid was given, 5,133 were cured and 11,712 died. It may strike you that we used too largely, patent unknown drugs. I plead guilty to the charge, but my plea for doing so was partly that many of them were asked for by the temporary medical subordinates that were employed for the medical relief work, and partly that I wanted to give a fair trial to some of the patent cholera cures that find such ready market in India, and once for all to pronounce for or against them. I now take this opportunity to record unhesitatingly that by the use of these vaunted cholera cures by amateurs much useful time is lost. If the State has no power to suppress them, I trust the authoritative voice of the profession will guard the public against them.

In my opinion alcohol is unnecessary in the treatment of cholera. In the collapse stage, small quantities of champagne with soda water may be given as a rapid stimulant, but spirits are seldom indicated, and I have never seen any good arising from them. I know of a gentleman who, when travelling alone over the Himalayas, had a smart attack of diarrhoea and vomiting. He had nothing with him but whisky to which he helped himself freely and was cured. During the epidemic in Kashmir he most sanguinely advocated to me the use of whisky. Similarly, another gentleman thought he had discovered the specific for cholera after one day curing his servant from an attack of cholera, as he thought, by the administration of Worcester sauce in the absence of anything else in the house that he could think of!

It must be admitted that our therapeutic resources for the treatment of cholera are still very unsatisfactory. In the *Civil and Military Gazette* of 16th June 1892, a medical gentleman advocated mustard emetic, and quinine and calomel, and the writer said that he always tried this mode of treatment having never failed in one single instance and guaranteed 95 per cent. of cures! As soon as I read this, I tried these medicines, following the writer's instructions, in 5 cases of cholera. Two died and one recovered, the latter making very slow progress. This hardly requires any comment. If we can catch the disease young, we

often succeed in cutting short an attack. In fact, by the judicious use of opium and astringents in the early stage, we can cure 30 per cent. of cases. When, however, the disease is unchecked and when the evacuation stage is advanced, bordering upon the next stage of collapse, drugs are useless; careful nourishing is then the only helpmate to struggling nature. Recovery or death depends upon the extent of mischief produced by the germs and their toxic products, the constitution of the patient, and the vital resistance which his tissues are able to offer to the toxic products. During the stage of reaction, however, judicious treatment is of the greatest value, and many a life has been lost by neglect in this stage of the disease. It is not a cholera mixture nor a cholera pill which should then be depended upon, but the symptoms of every particular case must be carefully observed, weighed and treated on principles based on rational medicine. The average mortality in fully-established cholera cases is about 60 per cent. in the beginning of the epidemic, 50 per cent. during its course, gradually falling to 25 per cent. or less, at the end of the epidemic. Any drug to have a distinct curative effect must reduce this mortality by at least 15 per cent.

I am therefore of opinion that, until further scientific researches into cholera and its treatment throw more light on the nature of the disease and the weapon best suited to fight with it, "a guarantee of 96 per cent. of cures" cannot be made by a scientific physician. The subject of the treatment of cholera is much complicated by the publication of immature hypotheses, and unless a physician is fully aware of the ground on which he is standing, he will jump from one drug to another till at last he realizes his position. The bacteriologist, the epidemiologist and the practical physician have each to contribute his own quota. The results of their researches, and their experience when collected together, will probably open out to us a vista of possibilities in successfully coping with the disease.

With these remarks, gentlemen, I beg to introduce to you the subject of the treatment of cholera, and I have no doubt that discussion would throw much useful light on this important subject. This is the first great assembly of physicians in modern India. I say modern India because there is evidence of Medical Congresses in ancient India; for CHARAKA, the great Hindu physician, says:—"An assembly of physicians is the foremost of all things that contributes to certitude of diagnosis"; also "Conversation and discussion with a professor of the same science is the foremost of all things that contributes to vigour of the understanding." I trust with CHARAKA, that conversation and discussion on this important subject will lead to a better understanding of the therapeutics of cholera.

CAUSES OF ILL-HEALTH OF HINDU WOMEN AND CHILDREN.

By HARA KALI SEN, V.L.M.S.,
Lalganj, Dinajpur.

In "Woman in India" Miss BILLINGTON says: "If I can only convince some of those who vote away blithely in a confidence as profound as their ignorance, upon matters which as grave issues of life, send death to our Eastern fellow-subjects of the Crown, that Indian women are not

altogether in such a pitiful plight, as some of their so-called friends come and tell us, my inquiries will not have been made in vain." MISS BILLINGTON'S inquiries are not only made in vain, but they are calculated to keep our women more in pain, as her defence of early marriage and Zenanas are not based on facts. As a flying visit to India is not sufficient for a foreigner in which to learn all the good and evil effects of our social and religious customs, I would advise MISS BILLINGTON to read "Kamala," the story of a Hindoo girl's life, in English.

Early Marriage.—MISS BILLINGTON, says: "Inaccurate sensationalism reaches its climax over the system of child marriage. The assiduously circulated idea of missionary reports and social grievance seekers is, that the wretched girl-infant is married at about 5 or 6 years of age, generally to some one vastly older than herself, who takes her away whenever he pleases, and exercises whatever violence or brutal lusts he cares for." "The ceremony of infant marriage is a mere form of betrothal." It is not a mere form of betrothal, but it is a regular marriage. If it is a betrothal, why are girls allowed to lie on the same bed with their husbands? And Government would not have been obliged to raise the age of consent from 10 to 12 years, in the face of such tremendous opposition and widespread dissatisfaction of Indian people. None can deny the truth, that before the menstruation of child-wives, attempts for coitus are often made with disastrous effects on the health, and sometimes lives, of our girls. If it is a mere form of betrothal, why are the girls not allowed to marry after the death of their would-be husbands?

Enforced widowhood and polygamy.—Widows have better health than our married women, whose health is shattered by annual child-bearing and rearing up children. Though our widows are free from diseases of the generative organs, yet they suffer from disorders of the digestive system, neuralgia, hysteria and other nervous diseases. Mentally they suffer from melancholia, which is one of the causes of many of the suicides, among Hindu women. I described in the *Record* the horrors of *Akulashi*, which compels the widows of the higher castes to fast twice in a month, for 24 hours, without even a drop of water in the hottest days of May, when men in Calcutta drink plenty of ice-water, but still die of sun-stroke and heat apoplexy. MANU, the great Hindu law-giver, says:—"In no *Shashtra* is there any advice to chaste women to take a second husband after the death of the first." (Manu Sanhita Chap. V verse 162). But see what he says next: "If the wife dies first, you should, after performing the cremation and funeral ceremony, marry again." (Chap. V. verse 168). In Hindu society a man can marry as often as he likes, but the most degraded form of polygamy exists in the society of *Kulin Brahmins*, among whom, even graduates are marrying more than one wife and polygamy is increasing the number of widows. "An idea may be formed of the extent to which the marriage of infants is prevalent in Lower Bengal, from the statistics given in the last census returns which shew 30,332 married girls and 6,780 married boys under 4 years, while there are 6,780 widows under the same age. The number of married girls of, and under 10 years was 378,754, while that of widows of the same age was 13,998."

Want of education.—Thanks to LADY DUFFERIN and a few others, female education in India is daily progressing. But it is not complete, only partial, because though progressing in Native Christian and Brahmo societies, it is not allowed to enter the zenanas of the Hindus and Mahomedans. In Hindu society, girls of 12 years are not allowed to go to school, and are confined within the prison of a zenana. Female education is not allowed by MANU, who says: "Women have no right to read *Souritics*, *Vedas* and other religious *Shastras*. They have also no right to any mantra; for this reason they are very low and worthless." (Manu Sanhita, chap. IX. verse 18). One of the causes of ill-health of our women is their ignorance of the laws of hygiene, and this ignorance of the mothers, causes ill-health in their children. For example, a Hindu mother believes that the more she feeds her infant the more she improves its health and quite unaware of the dangers of overfeeding, she gets a large cup of milk, which, regardless of its cries or unwillingness, she continues to force down its throat till she finds that its belly is enormously distended. This overfeeding is one of the principal causes of hepatic diseases, as the diseased little liver is overworked for the chyliification of such a large quantity of milk at a time, and is not allowed to work freely, on account of the great pressure exerted on it. I remember when as a boy, I was often beaten by my female relatives for not taking, even when hungry, a bellyful of food. I was not allowed time to chew, but was advised to swallow as fast as I could the greatest quantity; within the shortest period, being their golden rule. As he who took time to eat was rebuked for his laziness. The mortality of Hindu children is a sufficient proof of the ignorance of our women. "Of every 1,000 European children born in Calcutta, 58 die before they reach the age of one year. Among Eurasians and mixed races, the death rate in the first year of age is 306 per 1,000 born, among Hindus, 315; and among Muhammedans, 363 die before they are a year old in every 1,000 born annually." The ratio of deaths of Hindu and Muhammedan children to European children is 6 : 1.

Zenana.—Pure air, light and cleanliness are demanded for health, but unfortunately these cannot be obtained within Hindoo and Mahomedan zenanas, where there are neither doors nor windows in the outside of the quadrangle through which the women inside and men outside might perchance see each other; and in deliberately and jealously trying to shut out our neighbour's gaze, we shut out pure air and light, converting our dwellings into dungeon-keeps, where we immure our wives and increase the mortality of our infants, who are never permitted in the open air, lest they come under the influence of *Bataah* (evil air) or *Drisht* (evil sight). Referring to the malhygiene of a zenana, a trenchant writer says of a rich native's palace: "We need not point out how dangerous this state of things is, how low the state of health among the women and children, and how terrible the result were cholera to enter the town in which such a palace stands! What ought to be done in such a case? It is too bad to be mended, and should therefore be ended."

Female education and emancipation, instead of being a luxury indulged in by fashionable England-returned babus, have become a necessity among the natives, so that

MISS BILLINGTON's argument that because a few Mahomedan ladies elected to preserve the zenana, Indian women, as a whole, are not eager for emancipation is as sensible as the theory that a caged bird prefers the cage to freedom, simply because it does not know what freedom is; but let that same bird have the enjoyment of flying about for a little while, and instead of being a nest as heretofore the cage becomes a prison. Is MISS BILLINGTON aware that in some districts of Bengal a daughter-in-law dare not speak to, or look at her mother-in-law or any of the elderly women of her household? Has she read that MANU teaches (Chap. IX, verse 2) that husbands and male relatives should not allow a woman out of their sight or to occupy an independent position, because they are base sensual creatures, who estimate a man not by his beauty, age or intellect, but by his ability to gratify their lust, and that they are adulteresses or harlots by nature and choice: living a chaste life only when prevented by opportunities for immorality. Does she know that the Hindu husband must be worshipped as a god (Chap. V, verse 154), and that no matter how vile, how base, or how unfaithful he may be to her, the wife has no moral right to hate him whose bond-slave she is? Cruel as these laws of MANU are, they are not dead-letters, and many a woman commits suicide to escape the brutal treatment she is subjected to if she does not give an unworthy husband the love and respect he demands from her. While they firmly believe that very few Western ladies are chaste, conservative Hindus boast of the chastity of their own women and oppose all attempts to emancipate them because they construe harlotry as synonymous with freedom, and the abolishment of the zenana. If Hindu zenana creatures be proud of their chastity under pressure of vigilant eyes, prisoners in jail ought to be equally proud of being virtuous by being denied the opportunity to sin. Educated revivalist Hindus bitterly oppose female advancement and ridicule, revile, condemn and spurn the Brahmo ladies from pulpit, stage and platform whenever they can get the chance, simply because the latter move freely in society; but strong though the tide of opposition is, the time will yet come when, in spite of MISS BILLINGTON's cry of "no necessity nor desire for emancipation" the murderous prejudices and superstitions of MANU will be swept wholesale out of India.

Social status.—For the woman there is nothing but tyranny and oppression, as Hindu society thinks it a disgrace for a man to enquire into his wife's affairs or attend her when she is ill, and MANU says:—"Do not eat with your wife (Chap. IV verse 43) and do not see her when she eats." Whatever is good and wholesome should be preserved for the men, and after the men have eaten the women may partake of what is left on their plates (i.e. the *prasad*). Consequently, what do our women eat? Whatever is rotten or is rejected by the male members of the household, or she must starve. Bad food and privation make her ill, but no one bothers his head about giving her medicine. When I was practising at Mohadebpore, a respectable youth came to me and surreptitiously pulling a phial out of his pocket said: "Doctor Babu! my wife gets fever daily, but she still works hard, and though she has become very weak and lean, no one ventures to give her any medicine, and

I myself dared not attempt to do so in the presence of others, lest I may be despised as a hon-peaked husband. If you prepare some medicine I will take it home this evening and give it to her secretly." The poor woman no longer lives to be crushed down by Hindu society. During life she was no better off than any other daughter-in-law who is and must be the early morn to midnight drudge of a huge array of relations-in-law and woe, woe to her if she infringe an iota of the cursed social laws that claim her serfdom.

Legal status.—None, absolutely none. A Hindu, who had two wives and was a profligate and drunkard, was still respectable (?) because he was a man and not a woman. Living with his second wife he cruelly ill-treated his first one, who ran away to her father's house and refused to return to her husband, who immediately proceeded against her for restitution of conjugal rights and got her imprisoned under section 200 of Criminal Procedure Code.

What an unjust law! How cruel? and still MISS BILLINGTON pleads that our women do not wish to be emancipated. So long as her husband lives, the Hindu woman can claim maintenance; but should she be left a widow without any private means of her own, the Hindu law does not provide for her in the absence of male issue by her husband, nor is anyone legally bound to support her. Thus:—"My father, who is living, has some property, while I have nothing; but I have four brothers, a wife and two daughters. Now if I die my wife has no claim on my father, nor on her father's property, which her brothers would inherit, and though I have many well-to-do relatives, not one of them is legally bound to support her; but should she have borne me a son and that son be alive, at the time of my decease, things would be just the reverse. In the face of all this will MISS BILLINGTON still persist in maintaining that our women are not in a pitiful plight and that they do not desire emancipation?

—O—

REPORT OF SURGICAL OPERATIONS PERFORMED AND MEDICAL WORK DONE DURING 1894-95 IN THE JUNAGADH STATE HOSPITAL.

By T. M. SHAH, L.M.S.

Chief Medical Officer, Junagadh.

(Continued from page 6, Vol. IX).

Radical cure of Hernia: unsuccessful; tetanus: recovery.—DEVNAR BHOGA had left inguinal scrotal reducible hernia of enormous size of three years' standing. It was operated upon for radical cure on 14th June 1894. After the usual incision, the sac could not be well separated; it was therefore invaginated and the pillars brought together by catgut, and antiseptic dressing applied.

19th.—Temperature varies between 98° and 101°. Patient suffers from cough; the part is painful and tender. Dressing changed as suppuration appears to have set in. Bowels constipated since operation. The thigh is semi-flexed and cannot be fully extended.

22nd.—Cough continues. Bowels moved four times.

30th.—Stools dysenteric, griping and tenesmus. Patient very restless and distressed. Prescribed anti-dysenteric pills.

2nd July.—Has got lockjaw and spasm of muscles of the neck.

3rd.—Spasm of all the muscles of the body, deglutition difficult. Prescribed chloral hydrate and potass bromid.

5th.—Hernia has descended into the scrotum. Spasm ceased. Wound healed up and discharged.

Strangulated Hernia.—PRATONJI, male aged 54, suffers from right scrotal hernia since many years. It became strangulated this afternoon.

1st September 1894.—Taxis, inverted position, fomentation and enema could not succeed in reducing it. The symptoms became aggravated. Operation was then to be performed; but, as a last resource, he was given hot hip bath, and while in water, taxis succeeded in reducing it. He had subsequently a sharp attack of diarrhoea.

2nd.—GHO HAUSA, aged 50, 7th July 1894, suffers from right inguinal hernia since seven years. It has not yet descended into scrotum. Since a week it has come down and is strangulated. Bowels constipated and patient vomits on taking anything into the stomach. Rupture is hard, painful, without impulse and without any symptoms of peritonitis. Patient was placed in inverted position, fomentation was applied and an enema administered. The next day he passed a motion, and from thence made gradual recovery.

Hydrocele.—P. N., aged 42, had a hydrocele of the left scrotum. It was tapped on the 19th February 1895. One pound of serous fluid was withdrawn and $1\frac{1}{2}$ drams of tincture of iodine injected into the tunica vaginalis. Patient discharged well on the 28th February 1895.

Hydrarthrosis.—RANO JESA suffers from hydrarthrosis of the left knee. The joint was aspirated and 4 oz. of clear fluid removed on 1st August 1894. The joint was strapped with mercurial plaster.

Two ovariectomies were successfully performed during the year:—

1. **AVAL**, female aged 40, was admitted with ovarian dropsy in August 1893; the abdominal tumour having the appearance of a gravid uterus. The tumour was inclined to the right side, and uterus anteverted. She had three children. The last one was born about 18 months ago. Menstruation was irregular. Abdomen was tapped and 164 oz. of grumous fluid were withdrawn. After this evacuation a solid floating tumour yet remained without any distinct trace of origin or attachment.

She was re-admitted in February 1894 with re-distension of abdomen. Again the tumour was inclined to the right side and was full in the upper part, as if it were connected with the liver, the hypogastrium being comparatively empty.

Ovariectomy was performed on the 6th March 1894 by making an incision in the middle line, commencing three inches above the umbilicus, and carrying the incision to an inch below this point. After opening the peritoneum the hand was passed in and a few adhesions were broken down; the cyst was then punctured with trocar and canula and 144 oz. of a thick viscid dark fluid evacuated. A small quantity of fluid escaped by the side of the canula and passed into the abdomen. After thus draining it, a large growth remained, which could not come out of the wound. On again examining the part with the hand it became evident that the cyst originated in the left ovary.

The wound was then enlarged downwards and the growth extracted. The pedicle consisted of the entire broad ligament, including the Fallopian tube. It was ligatured with silkworm gut and then replaced into the pelvic cavity; sutures and iodoform dressing were then applied to the abdominal wound.

The cyst was multiple, the growth being another cyst inside the mother cyst.

The subsequent progress was satisfactory. The highest temperature on the 3rd day was 101° , the pulse 108, and respiration 30, but they were all reduced to normal on the 5th day after operation. She partook of milk sparingly for the first two days, arrowroot was given on the 3rd day. She complained of pain on the 6th day, an enema was therefore given which acted freely. She then had daily motions, and passed urine voluntarily throughout, after the operation. Abdominal wound united by first intention. Primary dressing was changed on the 12th day and sutures were then removed; she was discharged well on the 6th April 1894—a month after the operation.

2. **VALLI**, female aged 35 years, admitted with ovarian dropsy on February 1895, the growth was noticed first says the patient, some years ago in the right iliac region. It gradually increased to the present dimensions. Abdomen is now distended to the full, measuring 39 inches in circumference. Her husband died 20 years ago, shortly after her marriage, and she had never conceived. Catamenia were regular, but have not appeared since three months. Abdominal tumour is fluctuating in some parts, but gives a solid feel in others. Uterus anteverted. She was suffering from bronchial cough.

Ovariectomy was performed on 6th February 1895. An incision, about 3 inches long was made in the middle line, commencing below the umbilicus. On opening the peritoneum the white glistening wall of the cyst was exposed. The incision was then enlarged to the extent of $1\frac{1}{2}$ inches above the umbilicus; the cyst was tapped and 375 oz. of dark thick oleaginous fluid withdrawn. A small quantity of this fluid escaped by the side of the canula into the abdominal cavity. The empty cyst was pulled out, there being no adhesions, when it was found to have originated from the left ovary. The entire left broad ligament and Fallopian tube were adherent. This broad pedicle was tied with silkworm gut and replaced into the pelvic cavity, which was next sponged; the abdominal wound was then sutured with silk and iodoform dressing applied. Pad and bandage were then put on.

3th February.—She was given simply ice and milk and opium and quinine pills.

12th.—Her temperature varies between 98° and 100° . Pulse 96 to 110. Respiration 22 to 28. Urine has to be withdrawn daily. She is now given milk and arrowroot. No pain whatever in abdomen. She suffers from cough. Opium and quinine pills continued.

14th.—Temperature 101° . Pulse 120. Respiration 36. Complaint of pain in hypogastrium and desire to pass stool. Olive oil was therefore injected into the rectum but without effect. Passes urine voluntarily. Urine had to be withdrawn for the first three days.

16th.—Primary dressing of abdomen changed. Wound united by first intention. No discharge whatever. There is a

and the surrounding swelling over the hypogastrium. It is not so much as painful. The patient feels no pain even while coughing. Gavage of warm water was given.

During the next two or three days she passed copious mucus, and the swelling disappeared, shewing that it was due to accumulation of feces.

17th.—Temperature 97°3. Pulse 96. Respiration 24. She is comfortable but her cough is getting more troublesome, she is not able to expectorate freely and respiration is wheezing. She sits up in bed and has now begun to take solid food. Prescribed stimulants and expectorants.

18th.—Cough is constant and expectoration more difficult especially during the night. Temperature 98°. Pulse 92. Respiration 22.

20th.—Stimulants and expectorants continued, but the cough became more troublesome, the respiration labored, and she died this afternoon.

Post-Mortem.—The abdominal wound had perfectly united, the intestines and other organs in the upper part of the abdomen were normal in appearance, those in the pelvic region were agglutinated together by lymph effusion. There was no sign of suppuration or degenerative inflammation.

Both the cases were alike in the seat of origin of the cyst; on the left side in both, the broad ligament and Fallopian tube were removed. Both operations were performed strictly antiseptically, and so far as the operations were concerned, both were successful. The latter case succumbed to the aggravation of bronchial inflammation to which the patient was subject, even before the operation was undertaken.

Symphiotomy.—MANEK DEYCHAND, a female, had two children, and suffered from backache and lameness. On vaginal examination, considerable antero-posterior contraction of the pelvis was found, and the sacral promontory was deviated a good deal forward. She became pregnant and was brought to hospital at full term with the os fully dilated. The antero-posterior diameter of the pelvis was hardly 2½ inches. Forceps and version were inadmissible, and the only alternative was either Symphiotomy or Caesarian section. The former was, of course, preferable, and was resorted to with success. After anaesthetising the patient, the ligament and cartilage of the symphysis pubis were divided by a bistoury and then within half an hour a male child was delivered. The separation of the pubic uni was very marked during the delivery. The child died the next day, but the mother made a good recovery.

Difficult labour: delivery by forceps.—JEVI GAXHADAR aged 32, primipara, had labor pains since five days. Membranes were ruptured, the head presented in the 2nd position. It was impacted in the cavity, and a large caput succedaneum had formed. The patient was watched for 12 hours, but the head made no progress. On the 21st January 1894, the patient was anaesthetised and a still-born male child was delivered by the forceps. She made a good recovery.

Tetanus Letor.—GANGA BAIJAN, Hindoo female, 30, 45 years, 1 para, had labor pains for 24 hours, since the 1st May 1894. Delivered of a female healthy child at 4-30 a.m. Discharged well 12th May 1894.

Placenta Praevia.—M. formula, multipara, reached the full term of her fifth pregnancy. Labor set in with excessive hemorrhage: for three days the patient did not allow an examination of the parts, but on the fourth day, when in extremis, medical aid was sought. She was extremely weak, and the bleeding continued. She was anaesthetised and a hand was introduced into the uterus; the membranes were ruptured, the child turned and delivered by the foot. Patient died an hour afterwards of sheer bloodlessness.

Tracheotomy.—Parashottam N. was admitted with syphilitic laryngitis on 7th August 1894. His palate was perforated, the nose depressed from destruction of cartilages and septum. Voice was hoarse; respiration wheezing and labored; deglutition difficult. He could not sleep. He was prescribed iodide of potassium and perchloride of mercury. On the 15th of August, tracheotomy was performed, troublesome venous bleeding had to be arrested before opening the tube. On opening the trachea, a large quantity of phlegm came out. As the breathing was not regular, a vulcanite tube was substituted for a silver one already introduced. He progressed favorably a few days, but a large quantity of discharge was thrown out of the tube daily, and he at last succumbed a fortnight after the operation.

Facial Neuralgia: Excision of Infra-orbital Nerve.—KHANDAI DAOODJI, aged 52 years, suffers from paroxysmal pain and twitchings of the muscles of the right side of the face. Pain starts from below the orbit and extends to the cheek and lip. He was treated with exalgin, potass. iodid, antipyrin and morphia injections. Some suspicious teeth from the right upper jaw were extracted without any benefit whatever.

On the 16th December 1894, the patient was anaesthetised and a vertical incision made over the right cheek at the lower margin of the orbit and another transverse one along the orbital margin. The tissues were dissected and the infra-orbital nerve exposed at its exit from the infra-orbital foramen, where it radiated in three filaments. It was raised, stretched and about ½ inch of it was excised. The wound was treated antiseptically. Patient was discharged well on 3rd January 1895.

Neuralgia of the Crural Nerve.—A man was admitted with neuralgic pain along the crural nerve on the right thigh, leg and foot. He was treated with embrocations, exalgin, morphia injections and electricity, but to no effect. He was discharged on 14th April 1894.

Fatty Tumour.—K. D., aged 40, had a large pendulous fatty tumour about the size of a melon, situated on the back, of 16 years' standing. For 12 years it was small and stationary, and then increased rapidly during the next four years. On 9th April 1894, the patient was anaesthetised and the growth removed. Although treated antiseptically, the wound suppurated and healed by granulation.

Cystic Tumour.—(1). V. R. had a cystic tumour about the size of a walnut on the left cheek; the skin was adherent. On the 22nd April 1894, patient was anaesthetised and the cyst dissected out. While dissecting it, the cyst burst and a cheesy matter exuded from it. A button hole was accidentally made in the skin. Wound healed by first intention.

2nd July.—Has got lockjaw and spasm of muscles of the neck.

3rd.—Spasm of all the muscles of the body, deglutition difficult. Prescribed chloral hydrate and potash bromid.

5th.—Hernia has descended into the scrotum. Spasm ceased. Wound healed up and discharged.

Strangulated hernia.—PASTORI, male aged 54, suffers from right scrotal hernia since many years. It became strangulated this afternoon.

1st September 1894.—Taxis, inverted position, fomentation and enema could not succeed in reducing it. The symptoms became aggravated. Operation was then to be performed; but, as a last resource, he was given hot hip bath, and while in water, taxis succeeded in reducing it. He had subsequently a sharp attack of diarrhoea.

2nd.—GREG HAUSA, aged 50, 7th July 1894, suffers from right inguinal hernia since seven years. It has not yet descended into scrotum. Since a week it has come down and is strangulated. Bowels constipated and patient vomits on taking anything into the stomach. Rupture is hard, painful, without impulse and without any symptoms of peritonitis. Patient was placed in inverted position, fomentation was applied and an enema administered. The next day he passed a motion, and from thence made gradual recovery.

Hydrocele.—P. N., aged 42, had a hydrocele of the left scrotum. It was tapped on the 19th February 1895. One pound of serous fluid was withdrawn and 1½ drams of tincture of iodine injected into the tunica vaginalis. Patient discharged well on the 28th February 1895.

Hydrarthrosis.—RANO JESSA suffers from hydrarthrosis of the left knee. The joint was aspirated and 4 oz. of clear fluid removed on 1st August 1894. The joint was strapped with mercurial plaster.

Two ovariectomies were successfully performed during the year:—

1. AVAL, female aged 40, was admitted with ovarian dropsy in August 1893; the abdominal tumour having the appearance of a gravid uterus. The tumour was inclined to the right side, and uterus anteverted. She had three children. The last one was born about 18 months ago. Menstruation was irregular. Abdomen was tapped and 164 oz. of grumous fluid were withdrawn. After this evacuation a solid floating tumour yet remained without any distinct trace of origin or attachment.

She was re-admitted in February 1894 with re-distension of abdomen. Again the tumour was inclined to the right side and was full in the upper part, as if it were connected with the liver, the hypogastrium being comparatively empty.

Ovariectomy was performed on the 6th March 1894 by making an incision in the middle line, commencing three inches above the umbilicus, and carrying the incision to an inch below this point. After opening the peritoneum the hand was passed in and a few adhesions were broken down; the cyst was then punctured with trocar and cannula and 144 oz. of a thick viscid dark fluid evacuated. A small quantity of fluid escaped by the side of the cannula and passed into the abdomen. After thus draining it, a large growth remained, which could not come out of the wound. On again examining the part with the hand it became evident that the cyst originated in the left ovary.

The wound was then enlarged downwards and the growth extracted. The pedicle consisted of the entire broad ligament, including the Fallopian tube. It was ligatured with silkworm gut and then replaced into the pelvic cavity; sutures and iodoform dressing were then applied to the abdominal wound.

The cyst was multiple, the growth being another cyst inside the mother cyst.

The subsequent progress was satisfactory. The highest temperature on the 3rd day was 101°, the pulse 108, and respiration 30, but they were all reduced to normal on the 5th day after operation. She partook of milk sparingly for the first two days, arrowroot was given on the 3rd day. She complained of pain on the 6th day, an anæmia was therefore given which acted freely. She then had daily motions, and passed urine voluntarily throughout, after the operation. Abdominal wound united by first intention. Primary dressing was changed on the 12th day and sutures were then removed, she was discharged well on the 6th April 1894—a month after the operation.

2. VALLI, female aged 35 years, admitted with ovarian dropsy on February 1895, the growth was noticed first says the patient, some years ago in the right iliac region. It gradually increased to the present dimensions. Abdomen is now distended to the full, measuring 39 inches in circumference. Her husband died 20 years ago, shortly after her marriage, and she had never conceived. Catamenia were regular, but have not appeared since three months. Abdominal tumour is fluctuating in some parts, but gives a solid feel in others. Uterus anteverted. She was suffering from bronchial cough.

Ovariectomy was performed on 6th February 1895. An incision, about 3 inches long was made in the middle line, commencing below the umbilicus. On opening the peritoneum the white glistening wall of the cyst was exposed. The incision was then enlarged to the extent of 1½ inches above the umbilicus; the cyst was tapped and 375 oz. of dark thick oleaginous fluid withdrawn. A small quantity of this fluid escaped by the side of the cannula into the abdominal cavity. The empty cyst was pulled out, there being no adhesions, when it was found to have originated from the left ovary. The entire left broad ligament and Fallopian tube were adherent. This broad pedicle was tied with silkworm gut and replaced into the pelvic cavity, which was next sponged; the abdominal wound was then sutured with silk and iodoform dressing applied. Pad and bandage were then put on.

8th February.—She was given simply ice and milk and opium and quinine pills.

18th.—Her temperature varies between 98° and 100°. Pulse 96 to 110. Respiration 22 to 28. Urine has to be withdrawn daily. She is now given milk and arrowroot. No pain whatever in abdomen. She suffers from cough. Opium and quinine pills continued.

14th.—Temperature 101°. Pulse 120. Respiration 36. Complaints of pain in hypogastrium and desire to pass stool. Olive oil was therefore injected into the rectum but without effect. Passes urine voluntarily. Urine had to be withdrawn for the first three days.

16th.—Primary dressing of abdomen changed. Wound united by first intention. No discharge whatever. There is a

seen was increasing swelling over the hypogastrium. It was tender but not painful. The patient feels no pain even while coughing. Enema of warm water was given.

During the next two or three days she passed copious solid stools, and the swelling disappeared, allowing that it was due to accumulation of feces.

17th.—Temperature 97°3. Pulse 96. Respiration 24. She is comfortable but her cough is getting more troublesome, she is not able to expectorate freely and respiration is wheezing. She sits up in bed and has now begun to take solid food. Prescribed stimulants and expectorants.

18th.—Cough is constant and expectoration more difficult especially during the night. Temperature 98°. Pulse 92. Respiration 22.

20th.—Stimulants and expectorants continued, but the cough became more troublesome, the respiration labored, and she died this afternoon.

Post-Mortem.—The abdominal wound had perfectly united, the intestines and other organs in the upper part of the abdomen were normal in appearance, those in the pelvic region were agglutinated together by lymph effusion. There was no sign of suppuration or degenerative inflammation.

Both the cases were alike in the seat of origin of the cyst; on the left side in both, the broad ligament and Fallopian tube were removed. Both operations were performed strictly antiseptically, and so far as the operations were concerned, both were successful. The latter case succumbed to the aggravation of bronchial inflammation to which the patient was subject, even before the operation was undertaken.

Symphiotomy.—**MANEK DEVCHAND**, a female, had two children, and suffered from backache and lameness. On vaginal examination, considerable antero-posterior contraction of the pelvis was found, and the sacral promontory was deviated a good deal forward. She became pregnant and was brought to hospital at full term with the os fully dilated. The antero-posterior diameter of the pelvis was hardly 2½ inches. Forceps and version were inadvisable, and the only alternative was either Symphysiotomy or Caesarian section. The former was, of course, preferable, and was resorted to with success. After anaesthetising the patient, the ligament and cartilage of the symphysis pubis were divided by a bistoury and then within half an hour a male child was delivered. The separation of the pubic ram was very marked during the delivery. The child died the next day, but the mother made a good recovery.

Difficult labour: delivery by forceps.—**JEVI GANGADAS** aged 32, primipara, had labor pains since five days. Membranes were ruptured, the head presented in the 2nd position. It was impacted in the cavity, and a large caput succedaneum had formed. The patient was watched for 12 hours, but the head made no progress. On the 21st January 1894, the patient was anaesthetised and a still-born male child was delivered by the forceps. She made a good recovery.

Prolonged Labor.—**GANGA BANNER**, Hindu female, aged 25 years, 1 para, had labor pains for 24 hours, since the 10th May 1894. Delivered of a female healthy child at 6.30 a.m. Discharged well 13th May 1894.

Placenta Praevia.—**M. female**, multipara, reached the full term of her fifth pregnancy. Labor set in with excessive hemorrhage; for three days the patient did not allow an examination of the parts, but on the fourth day, when in extreme medical aid was sought. She was extremely weak, and the bleeding continued. She was anaesthetised and a hand was introduced into the uterus: the membranes were ruptured, the child turned and delivered by the feet. Patient died an hour afterwards of sheer bloodlessness.

Tracheotomy.—**Parshotam N.** was admitted with *siphilitic laryngitis* on 7th August 1894. His palate was perforated, the nose depressed from destruction of cartilage and septum. Voice was hoarse; respiration wheezing and labored; deglutition difficult. He could not sleep. He was prescribed iodide of potassium and perchloride of mercury. On the 16th of August, tracheotomy was performed, troublesome venous bleeding had to be arrested before opening the tube. On opening the trachea, a large quantity of phlegm came out. As the breathing was not regular, a vulcanite tube was substituted for a silver one already introduced. He progressed favorably a few days, but a large quantity of discharge was thrown out of the tube daily, and he at last succumbed a fortnight after the operation.

Facial Neuralgia: Excision of Infraorbital Nerve.—**KHANNAH DAOODJI**, aged 52 years, suffers from paroxysmal pain and twitchings of the muscles of the right side of the face. Pain starts from below the orbit and extends to the cheek and lip. He was treated with exalgin, potass. iodid, antipyrin and morphia injections. Some suspicious teeth from the right upper jaw were extracted without any benefit whatever.

On the 16th December 1894, the patient was anaesthetised and a vertical incision made over the right cheek at the lower margin of the orbit and another transverse one along the orbital margin. The tissues were dissected and the infra-orbital nerve exposed at its exit from the infra-orbital foramen, where it radiated in three filaments. It was raised, stretched and about ½ inch of it was excised. The wound was treated antiseptically. Patient was discharged well on 3rd January 1895.

Neuralgia of the Crural Nerve.—A man was admitted with neuralgic pain along the crural nerve on the right thigh, leg and foot. He was treated with embrocations, exalgin, morphia injections and electricity, but to no effect. He was discharged on 14th April 1894.

Fatty Tumour.—**K. D.**, aged 60, had a large pendulous fatty tumour about the size of a melon, situated upon the back, of 16 years' standing. For 12 years it was small and stationary, and then increased rapidly during the next four years. On 9th April 1894, the patient was anaesthetised and the growth removed. Although treated antiseptically, the wound suppurated and healed by granulation.

Cystic Tumour.—(1). **V. R.** had a cystic tumour about the size of a supari on the left cheek: the skin was adherent. On the 22nd April 1894, patient was anaesthetised, and the cyst dissected out. While dissecting it, the cyst burst and a cheesy matter exuded from it. A button hole was accidentally made in the skin. Wound healed by first intention.

(2). R. N. had a small cystic growth at the inner angle of the left eye; it was dissected out and the wound healed by first intention.

(8). K. H., child *æt.* 3 years, had a congenital cystic tumour over the left lower lid. The eyeball was absent and the cyst-wall reached quite the apex of the orbital cavity. On 24th January 1895 the child was anaesthetised and the cyst dissected out.

(4). O. B., aged 20 years, had a cystic tumour of the size of an orange over the right external malleolus. Patient had a guinea-worm in this region some two years back. The cyst was dissected, but on 27th January 1895 it consisted of a jelly-like substance with a guinea-worm buried in it.

(5). C. S., aged 30 years, had a cystic tumour of the left thigh about the size of a cocoanut; it was globular, soft and fluctuating, and of 8 months' duration.

On the 15th July the patient was anaesthetised, and a vertical incision was made. The tumour was forcibly separated and burst, a brownish-thick fluid escaping, the cyst-bag was removed *entire*.

ECCIAS (1) A. N. male, had a hard tumour on the left cheek about the size of a lemon; on the 4th August 1894, the patient was anaesthetized, and an incision made into the gum; the growth was shelled out and its cavity plugged with lint. Patient was discharged well on the 16th.

(2). R. S., female, aged 40, had a large growth in the mouth, arising from the side of the upper jaw; deglutition and mastication were difficult. It was removed by evulsion.

Fibrous Tumour.—A. K., male aged 23, suffered from a fibrous tumour of the left parotid of the size of a mango. On the 14th February 1895, A. V.-shaped incision was made over the growth and the tumour dissected, but the wound healed by first intention.

(2). K. R. had an ulcerating growth on the left buttock; the surface of the ulcer was studded with bundles of white fibrous tissue. He had a horny tumour in the same region; it was removed four years ago. The patient was well for about two years, after which the growth re-appeared. Anaesthetised on the 21st January 1895, and the growth removed; wound healed by granulation.

Uterine fibroid polypus.—B. B., female aged 40 years, admitted 25th January, 1895, complaining of a sanaceous discharge from vagina, and anæmia.

On examination, a hard fibrous tumour, about the size of an orange was detected in the vagina with a thin pedicle, embraced by the os, having its origin in the uterus. The tumour was got rid of by an *œtaseur*.

A LARGE AND LONG-LIVED FAMILY.

A CORRESPONDENT writes to the *British Medical Journal*:—There has just died the last of a large family of fourteen—eight sons and six daughters. They all grew up. The youngest died at 23½ years, the oldest at 87½. The total age of the fourteen was 866 years, the average being 61½ years. The eight sons averaged 68 years, the six daughters 60½ years. Ten out of the fourteen lived 50 years and upwards, and their average age was 78½. The respective ages attained were: 25½, 27, 34, 44½, 50, 59, 67½, 71½, 76½, 79½, 79½, 84, 84½, 87½ years. It takes a large and long-lived family to cover a century. The father of this family was married April 3rd, 1795, and the last of his offspring died May 17th 1895.

A MIRROR OF PRACTICE.

THREE CASES OF PROTRACTED LABOR: INSTRUMENTAL INTERFERENCE.

By HARRY GIDNEY, D.M.C.C.

Assistant Civil Surgeon, Massachusetts.

CASE I.—On the 14th April 1894, I was called out to see a patient who was said to be in labor. I went over to the house and found my patient to be a primipara aged 17 years. Married two years. No miscarriages.

Present condition.—Very weak and exhausted. Pulse 132 per minute, and very thready. Respiration hurried. She gave a history of labor having started three days ago. Liquor amnii was evacuated on the previous Monday, labor pains had ceased since Tuesday at 2 P.M. I made a vaginal examination and found the os to be patulous, but dilated only to the size of a wineglass. Fœtal heart sounds were not audible anywhere. From the condition and history of the case, I considered it one of "uterine inertia." I administered chloral hydras 5j., in three doses, with no effect. Nature could not act here, so I decided on applying the forceps. Accordingly, I summoned another medical man in consultation, and the patient was placed under chloroform.

I then dilated the os with Barnes's bags to its fullest extent, and applied the long forceps and delivered the child, which had been dead from all appearances, for at least two days.

The patient being a primipara, I took off the forceps as soon as the head engaged the vagina for fear of rupturing the perineum. The placenta came away 25 minutes after the birth of the child. There was a very offensive smell from the parts, in consequence of which, I used a uterine douche of 1 in 1,000 perchloride, giving a vaginal douche as well. I applied a binder and gave the case in charge of the midwife. The usual mixture of quinine, ergot and digitalis was administered. The parts were douched thrice daily with 1 in 2,000 perchloride and the case made an uninterrupted recovery, being quite well on the 13th day after labor.

CASE II.—I was called in July 1894, in consultation with another local medical practitioner, to see a case of labor. When I saw the woman I found her to be in almost a similar condition as case No. I. Labor had started three days previously. Liquor amnii was evacuated on the 2nd evening of labor. Labor pains had ceased shortly afterwards.

Condition of the patient.—Age about 15 years, of small size as compared with her husband. Primipara. Pulse very weak and beating fast. Patient in an exhausted condition, due to the prolonged labor. The bowels were constipated, and thinking this caused the delay in labor, an enema was administered, but with no effect. On vaginal examination I found it to be a case of vertex iv. The os was dilated to the size of a wine glass. The parts were very warm to the touch.

The fœtal heart sounds were audible, but were very rapid and very weak, indicating failure of the child's heart.

I informed the other medical man that if the case was left to Nature, the patient would undoubtedly die. I therefore strongly advised the application of the forceps.

The patient was put under chloroform; the os dilated to its fullest size with Barnes's bags, the long forceps applied and the child delivered.

The cord was found to be wound round the child's neck, which was at once undone. The face of the child was greatly congested and purple, shewing great difficulty in breathing. He (the child) was placed alternately in cold and hot water, but died 12 minutes after its birth.

As our attention was almost entirely devoted to the child, the mother was left to herself, and when I looked at her, I found to my great surprise, that she was breathless. We immediately resorted to artificial respiration, and after 15 minutes' hard work, resuscitated life. My next thought was towards the placenta.

Half an hour, one hour, two hours had passed, and no placenta escaped. I therefore at once inserted my hand into the uterus and found that the cause of this delay was due to "Hour-glass contraction" of the uterus. I however passed my hand up through the contraction with great difficulty, using a rotatory dilating action, and tore the placenta from its attachments by force. This gave rise, to a good deal of hemorrhage, which ceased after a time.

Sclerotinic acid was then injected hypodermically, as the womb had not contracted to the cricket-ball shape, which sensation is so pleasant to the hand of the accoucheur! A uterine douche of 1 in 2,000 of perchloride was given and also a vaginal douche. A binder was applied and the usual P. P. mixture administered. Ether sulph was injected twice during the operation; the patient was perfectly well on the 15th day after labor.

CASE III.—On Tuesday night of the 19th March 1895, I received a letter from the Civil Surgeon, requesting me to attend a case of labor which was being sent to the Mussourie Hospital for treatment. I at once proceeded there and after a short while the patient arrived. After a careful examination, I elicited the following history from her:—Had one child two years ago; no history of miscarriages; age 32 years; labor pains started four days ago. Lignor annui had escaped on the first morning after labor started.

Present condition.—Very weak and exhausted from the effects of the prolonged labor. Pulse hardly perceptible, thready and irregular. Temperature about 102°F. Respiration hurried and difficult. On examination per vaginam, I found the os to be dilated to the size of a button-hole, or a little larger, but very patulous. The vagina was very hot to the touch. An extremely offensive smell came from the parts.

The case was one of vertex presentation, but as the presentation was high up in the pelvis, I could not discover the exact position of the child's head. The external appearance of the womb was very irregular and inclining more to the left side. This gave me the idea that it might be a case of twins. Great distension of the parts was also present. Her bowels had been moved a few hours before coming into hospital. She also passed urine freely.

The Civil Surgeon, accompanied by another medical man, came in to see the case. A vaginal douche of bichloride 1 in 500 was administered. After a careful examination,

the Civil Surgeon detected a large swelling lying in the posterior part of the pelvic cavity, which prevented the descent of the child's head into the outlet of the pelvis.

As Nature could not act, and as the swelling in the posterior part of the pelvis prevented the use of the forceps, the operation of Craniotomy was agreed upon.

The Civil Surgeon accordingly passed the perforator up, but could not pierce the skull, as the child's head receded higher up on the slightest pressure; this caused much delay. However, the child was steadied externally, and after a great deal of difficulty, the perforator entered into the skull and the brain was evacuated. The different bones of the skull were quite separate owing to the far advanced state of decomposition, being held together merely by the scalp. The crushing forceps were then applied and three bones of the skull extracted, *viz.* the two parietal and occipital.

The forceps was then applied to grasp the remaining portion of the head and so extract the child, but failed to do so, as the parts gave way on the slightest pressure exerted. I was then asked, having the smallest, sized hand, to do what I could. I passed my whole hand into the uterus, and to my great surprise, extracted two of the sternal ribs. I again introduced my hand and pulled down the right arm; a bandage was then tied to the wrist joint and slight traction applied, but as decomposition had advanced too far, the arm got disarticulated at the shoulder joint. I then tried to seize the left hand and by means of the blunt hook drew it out, but this also gave way when traction was applied. I next attempted to seize the legs of the child. I endeavoured hard to push my hand as high up as possible, but was to a certain extent prevented by the projection of the swelling in the posterior pelvic cavity, which was to all appearances an osseous tumour.

After a great deal of difficulty I managed to get the blunt hook round the hip-joint, and by its means drew down the right foot. I then tried to seize the other foot, but my hand was almost powerless by this time, so the Civil Surgeon took up the work at this stage, and by means of traction on the right foot, he drew out the left foot. By using slight traction on both feet the child was extracted, *minus* the remaining part of the skull, which was still in the uterus. The missing bones were the two temporal and the two frontal. (The face came out with the rest of the body). These four bones formed a kind of a ball which could not be got hold of owing to the projection of the bony tumour. I tried to put in the whole of my hand and extract the bones, but could not exercise sufficient traction. After trying all kinds of instruments the bones were finally extracted by the crushing forceps.

The above operation lasted from 10-30 p.m., Tuesday, to 2 a.m., Wednesday—about 3½ hours; the patient being under chloroform during the whole time. Sulphuric ether was injected four times during the operation.

The placenta had not come away as yet, so I put in my hand to extract it by force, but failed owing to the projection of the tumour. The offensive smell from the parts and from the child was the worst that any of us had ever experienced. As the patient was too much exhausted

THE Indian Medical Record.

16th July, 1905.

(SIR WILLIAM ROBERTS, M.D., F.R.S. ON THE
GENERAL FEATURES AND THE MEDICAL
ASPECTS OF THE OPIUM HABIT IN
INDIA) AND THE RECKLESSNESS
OF THE EVIDENCE ON WHICH
HIS CONCLUSIONS ARE
BASED.

THE above heading—in parenthesis—is the title of the memorandum on the medical aspects of the opium habit appended to the final report of the ROYAL COMMISSION ON OPIUM. We have waited patiently for this utterance from the distinguished physician, who was the independent medical expert on the Commission; and judging from what we had gathered from his previous writings, and the kind of evidence laid before him by Indian Government officials, we have in this memorandum just what might be expected. If we have to expose the devious ways of some of those who presented the medical aspects of the opium habit in India before the Commission, and to point out deliberate pitfalls into which the English members of the Commission have fallen on the medical side—for that is after all what concerns us most—SIR WILLIAM ROBERTS will only thank us for candid and fair criticism of what we think, the unstable evidence upon which he has built his report. We are quite well aware that he could not—from his want of personal knowledge of India, its peoples, its Government, and Local Governments and their ways—surmise that he was being misled by the evidence placed before him—facts being sometimes withheld which would change the whole significance of the evidence. But before we consider the memorandum itself, let us ask why SIR WILLIAM ROBERTS was selected as the medical expert at all? A medical expert who is chosen to decide any question in dispute between medical men ought to be one who has not committed himself on either side of the controversy. If a medical man has strong and pronounced views and fixed opinions on one side of the matter in dispute, it clearly follows that he at any rate is not a fit person to adjudicate in such a case. Thus, if SIR W. B. RICHARDSON, who is known to have very pronounced views regarding the effects of alcohol on the human organism, were to be selected as an expert to weigh evidence and finally to write an authoritative report which would settle the scientific social and physiological aspects of the alcohol question, an outcry would immediately be raised that the whole question had been put at the mercy of a bigoted temperance advocate. In the case of the Opium Commission, the medical expert selected should have been as free from partisan views as any expert required to report on the alcohol question. But what are the facts as regards SIR WILLIAM ROBERTS? He occupies the same position, in medical circles, regarding dietetics and food accessories (alcohol, opium, tea, coffee, &c.) as that occupied by SIR W. B. RICHARDSON in regard to alcohol. This will be made very apparent by the following brief quotations from his "*Lectures on Dietetics and Dyspepsia*," published ten years ago. He writes:—"The food customs of mankind

are therefore not to be viewed as random practices adopted to please the palate or to gratify an idle and whimsical appetite. These customs must be regarded as the outcome of profound instincts which correspond to important wants in the human economy." I need hardly say that these customs which are not the outcome of the free choice of the population, but are the consequences of legislative enactments or of religious injunctions, are of no utility as guides in the study of dietetics except indeed as warnings of the mischief that may accrue from ignorant meddling" (Lectures, page 5). Then he says "that the effects (of tea, coffee and cocoa) have not been injurious to the nations of Europe is demonstrated by the continued progress of these nations, and their increasing ascendancy among the nations of the world (page 10). We are amazed at this kind of reasoning as applied to dietetics and food accessories, which in this country (India) must of necessity include opium; and the absurdity of it will appear if we apply this to Asia instead of the "nations of Europe." If we substitute "opium" for "tea and coffee" and Asia for "Nations of Europe" in the above sentence, it would read thus:—"That the effects of opium have not been favorable to the material progress and advancement of Asia (especially India) is demonstrated by her backwardness, poverty, degeneration and continued grovelling dependence among the nations of the world. Indeed by the same process of reasoning China, an opium-enting nation, falls defeated and demoralised before Japan, an anti-opium nation, numerically seven times China's inferior!"

Yet another quotation:—"It would not appear to be the part of wisdom to depart without some solid reason from the dietetic customs of the country. We may be quite sure that the use of meat and of alcoholic beverages and tea and coffee (and now opium) subserve some useful purposes to the human economy, though we in our ignorance may not be able to specify them with precision. These customs are the spontaneous outcrop of natural instincts, and the fruit of an immense experience; and the sanction they derive therefrom constitutes an incomparably weightier authority than any other we possess." (Lectures page 13.)

From these few extracts it will appear that SIR WILLIAM ROBERTS had pronounced and fixed views entirely in favor of such food accessories as alcohol, tea, coffee, cocoa, (and, in India where opium is used, of opium). To select him therefore as the independent unbiased (?) medical expert of the Opium Commission was a wise and discriminating choice by the officials concerned; for he could not undo his lectures, nor reject opinion which had gained for him a certain reputation. The scientific world, however, had it known that these views were the pet theories of SIR WILLIAM ROBERTS would have rejected him as eminently disqualified to sit on any such Commission. Not only was he unfit to sit on the Commission by reason of his published views—these he might have held in abeyance if he chose—but the questions he put, or did not put, to anti-opium witnesses, betrayed his bias from the beginning. The anti-opium witnesses were apparently treated by him with scant courtesy. While the official witnesses, when uttering the merest twaddle and outrageous exaggerations were received with evident appreciation, as witnesses whose authoritative utterances must carry conviction to the most

... mind. As we have said, if the medical expert had been misled, hoodwinked, and betrayed into the error, glaring error, he is not to be blamed, because his knowledge of the people and their environments was of the most meagre and superficial kind. It was not so with the Indian medical and official witnesses; they knew the people, their habits, their climate; and they knew also, Sir WILLIAM ROBERTS'S theories on dietetics. It will not be amiss for us therefore to point out some details which might escape the ordinary reader of the Report, but which are quite known to all who know India and the opium question—details which will confirm all that we have said, and open the eyes of the public to the kind of evidence laid before the Opium Commission.

1.—*Distribution and prevalence of the opium habit.*—Under this head SIR WILLIAM ROBERTS writes—"The dual character of the opium habit, with its medicinal side and its euphoric side, explains some of the irregularities and anomalies in its distribution. The habit prevails in excess of the average among the peasantry in low-lying damp and malarious districts. It also prevails in excess of the average among the Rajputs and Sikhs, and in such cities as Lucknow and Benares, where there is a large class of idlers. In the former case the excess may be said to be due to the solicitations of the medicinal side, in the latter case the excess may be said to be due to the solicitations of the euphoric side of the habits." The term *euphoric*, here used, SIR WILLIAM tells us, means "feeling perfectly well and able to bear pain and anxiety easily." We have been accustomed to look upon opium as possessing two distinct qualities—*anodyne*, *hypnotic* and *astringent*; but here it is divided into the "*euphoric*" and *medicinal* or *antiperiodic*. For it is only its antiperiodic properties that would cause a demand for its use in low-lying, damp and malarious districts. That he had great difficulty in accounting for the peculiar distribution of the opium habit with his own theories before him is quite evident. It was this difficulty that induced him—very ingeniously we admit—to divide the drug into "euphoric" and antiperiodic—the former to suit Rajputana and the Punjab and the latter to suit Bengal, Assam and Orissa. He found that if he ascribed the prevalence of the habit to malaria, the habit was not found excessive in the most malarious districts; and if he tried to limit it to "low-lying and damp" districts, the uplands of Rajputana and the Punjab contradicted his theories. He was compelled very reluctantly to abandon the malarious theory as the only one applicable to the case and ingeniously split up the drug into two divisions that would give some show of plausibility to his theories as to the cause of the peculiar distribution of the opium habit. The striking point in Bengal is, that the most malarious districts show a minimum of consumption, and that healthy districts or provinces in which little or no malaria prevails, are excessive consumers of opium. It was very puzzling. But a man, prepossessed with a theory, is never at a loss! "The therapeutic effects of opium are much alike—tolerance apart—in all persons and in all climates; but it would seem as if only a select portion of the population were susceptible to its euphoric effects." It will occur to the Indian physician that these extraordinary physiological instincts of "a select portion of the population"—so different from European nations—are not only discriminative and selective as regards opium, but that whole provinces and races have developed

the peculiar instinct for appropriating only one side of the drug and that not its anodyne, hypnotic or antiperiodic qualities, but a new quality called "*euphoric*" or "*making to feel well*."—It has not occurred to SIR WILLIAM ROBERTS, or if it has, has been studiously ignored by him—that there are other facts which will satisfactorily account for the seeming anomalous and erratic distribution of the opium habit throughout the various provinces and districts of India. Let one official extract, which was passed by a conscientious official before this Opium Commission was talked of, suffice. MR. A. SYME, for years in the opium district of Gorakhpur, and for a time in charge of the Opium Agency, wrote in 1840:—"The people of the province of the people suffer from the production of opium. Wherever opium is grown it is eaten, and ... it produces the more it is eaten: its pernicious effects on the population of the opium districts, particularly in the neighbourhood of depôts.....one opium cultivator demoralises a whole village." (Hansard, Vol. 68, page 382). If we keep this one outstanding characteristic of opium cultivation before us, viz:—its power of fastening the opium habit upon the people who cultivate it, we have an efficient and reliable solution of the problem of the unequal distribution of the opium habit among the rural populations in India. In considering this question we must not look upon human nature as a sphinx, carved out of stone, neither liable to temptation nor possessing any power of imitation. On the contrary, we must remember that human nature, as it is, has a tendency to fall into habits, good or bad; and that these habits will bear a definite relationship to the proximity, number, and power of the temptations set before it. It will be found, in India that the distribution of the opium habit corresponds generally in rural tracts, with present or past areas of opium cultivation. Thus in Table III of the Commissioner's report, we find *Assam* heading the list for excessive consumption of opium in all the provinces in India. It has 141 grains per head per annum. MR. DRIESSEN, Commissioner of Excise, Assam, tells us "that when we first acquired Assam (I now speak of the Assam Valley) every villager grew his own opium;" and in their report the Opium Commissioners inform us that "previous to 1873—1874, permission to sell opium was granted free of payment." We have here then unrestricted cultivation and free sale of opium in Assam, for how long we do not know. This solves the mystery which so puzzled the expert on the Opium Commission. We in India never think of attributing the large consumption of opium in that unhappy province either to the euphoric or antiperiodic properties of the drug, far less to any instincts peculiarly developed in the Assamese race!

Berar comes next, with an average consumption per head per annum of 91 grains. Berar and the Central Provinces, especially those districts approaching the confines of the Malwa region, were all opium-growing districts prior to the date of annexation in 1854; some time after which the cultivation was stopped, and became limited to the Malwa region. The district of Ellichpur, in Berar, which shows the largest consumption—154 grains per head was an opium-growing district prior to 1854. Here again we see the same cause operating—opium cultivation, leaving its trail of the opium-eating habit behind it. The Bombay province with Sindhi comes next, and the Opium

Commission Report tells us that if we leave out of account the consumption in the city of Bombay, which is 155 grains per head per annum, "we find the high rate of 94 grains per head in Gujarat, where a considerable Rajput population is surrounded by lower classes with a marked habit of imitating Rajput customs;" (page 42, para 49), that is to say, the Gujaratis are a most imitative race. Neither "euphoric" nor antiperiodic, but imitative! As a considerable number of opium-eating Rajputs from the opium growing districts of Rajputana have found their way into Gujarat, the lower classes take opium to imitate them! We do not suppose that the official members of the Commission were ignorant of the following resolution—a trumpet-blast from the Government of Bombay in 1881. "III On the question of the expediency of permitting the cultivation of opium in Sindhu... III. I am at the same time to state that this Government considers there are very strong objections to the introduction of an industry so demoralising in its tendency as opium cultivation and manufacture into a province where it is at present unknown. . . . It has already been tried in Gujarat, and the result was wide-spread corruption and demoralization." Again we must correct the Commissioners. It is no longer "imitating" Rajputs that has demoralised the Gujaratis or caused the excessive consumption of opium in that province; nor is it even their "euphoric" instincts, but simply opium cultivation! This will be still more clearly seen if we compare, as the Opium Commissioner's Report does, the consumption in Gujarat with the consumption in the Kanarese country in the far south of the presidency, far away from the opium-growing centres, where the minimum consumption per head is only 4 grains. Let us now turn to the Punjab with the next largest consumption, viz., 42 grains per head. Dr. WATT states that "with the exception of the Punjab no other British province is allowed to grow the plant save in the tracts that have been brought under the direct supervision of the agencies of Patna and Benares" (East India Opium, p. 36). The Commissioners also admit that "within the Punjab itself no restriction was placed under the Sikh administration on the cultivation of poppy. . . . On the acquisition of the province by the British from the Sikhs, it would have proved a highly unpopular measure to prohibit the cultivation altogether, and in some places the prohibitions would have resulted in serious injury to the cultivators." This clearly and satisfactorily accounts for the Punjab occupying the fifth place on the list of opium-consuming provinces. It is matter for consideration not that the consumption of the Punjab is so high, but rather a matter to be explained why the consumption of licit opium is so low. There are two outstanding facts which meet us here: (1) the opium-growing tracts in the Punjab itself; and (2) the proximity of "protected states (where opium is cultivated) by which the province is bordered on two sides." From these circumstances it becomes apparent that the consumption of licit opium in the Punjab, large as it is—is but a fraction of the actual amount known to be actually consumed there.

The Central Provinces come next on the list, with a consumption per head per annum of 34 grains. Here again we are brought face to face with the same general cause of excessive consumption viz., opium cultivation.

The Opium Commissioner's Report states that "Gujarati consumption is no doubt greater than is shown by these figures. Most of the districts in these provinces were not annexed until 1854, and the free cultivation of the poppy allowed under native rule was not stopped till some time after annexation." But before we leave the provincial averages of consumption let us glance at the North West Provinces and Oudh, and notice the use the commissioner's make of Table III. which shows the consumption of opium in the various provinces of British India, and which we have been examining. They state that "a shop in Oudh for instance, suffices for more than 10 times the population served by one in the Central Provinces, Berar, or Assam, and for double the population for which a shop is provided in the densely-peopled province of Bengal." This is one of the most undisguised official plessantries played off at the expense of the British public, we have seen throughout the Report, and one of those mysterious facts which so puzzled Sir WILLIAM ROBERTS. The explanation of this very anomalous state of things regarding shops is very simple.

The Central Provinces, Berar and Assam were centres of previous opium cultivation—as we have shewn above—which left behind it—as a legacy to these unfortunate races—the opium habit. As opium is no longer grown in these provinces, illicit opium can only very sparingly be obtained in Assam, if at all; but is obtainable to a considerable extent in the Central Provinces and Berar, as they are in the vicinity of the opium-growing region of Malwa. In the province of Oudh, on the contrary, every district cultivates opium, or is permitted to do so, at this moment. Indeed, were it not for the large towns and villages existing in the districts of Oudh, where the inhabitants cannot have poppy fields of their own, there would be no need for any shops selling licit opium in the whole province. In paragraph 47 of their Report, the Commissioners seem to have realised the absurdity of para. 43, and return to the same subject with a little less confidence, adding, "but in the North-West Provinces the average annual consumption is returned at 24 grains per head. In Oudh, during Native Rule, which only ended in 1856, there was no restriction on cultivation or sale. The corresponding figure there falls to 15. It must be borne in mind, however, that the cultivation of poppy is permitted under license in every district in Oudh—a fact which in some degree accounts for the small consumption of licit opium. The existence of a large city in which the traditions of a corrupt Mussulman court have not yet been obliterated, explains probably the high rate of consumption in the Lucknow district, where it is seven times as high as that in the rest of Oudh." Lucknow's evil pre-eminence—asccribed to the "traditions of a corrupt Mussulman court"—has 106.8 grains per head per annum, while Calcutta with the high moral traditions of the British rulers of India, has a consumption of 276 grains per head! This seeming abnormality, which not even a Member of Parliament like Mr. MOWBRAY, could account for—an ordinary ryot from Oudh would explain in two words—illicit opium.

We do not for a moment suppose that the official members of the Commission were ignorant of this simple explanation, when they were manipulating the Report: that would be insulting their intelligence and general culture; but then, it was no part of their duty to play into

the ranks of the anti-opium party, and therefore they could not be expected to obtrude their own individual opinions upon the Opium Commission! The city of Lucknow is surrounded with opium-growing districts, and opium is constantly being smuggled into the city in large quantities: this accounts not for the high rate per head in Lucknow as compared with opium-growing rural Oudh, but the low rate in Lucknow as compared with Calcutta, where opium cannot be obtained, except through licit shops. The marked lowness of the rate per head in the opium-growing districts of Oudh, the Commissioners themselves explain by the fact of the widespread opium cultivation in every district. You might as well expect that a baker who has a bakery and shop of his own for selling bread should go for his daily supply of bread to the opposition Government shop across the road, as to expect that the opium cultivators of Oudh would use licit opium. The cities, however, require a word of explanation. The off-scourings of small towns and rural districts gravitate to the cities, where immoral influences and pressure for existence lower the moral tone of the people. If an Indian city has facilities for checking illicit traffic in opium, and is far removed from the opium-growing centres, the percentage of consumption per head will be high, as in Calcutta; but if, on the other hand, the city has an excessively large number of opium-consumers, and is surrounded by opium-growing districts—such as Lucknow,—the amount of licit opium consumption will only represent a fraction of what is actually consumed. Thus we think we have shewn from the Commissioners' own Report that the *distribution and prevalence of the opium habit* all over rural India bears no relation whatever to its medicinal qualities or to its "euphoric" side: but it does bear a distinct and definite relationship to the past and present cultivation of poppy in these districts and provinces, where it is excessively used. The seemingly anomalous consumption in the cities also, as we have seen, can be accounted for on other and more rational grounds, the far-fetched "*traditions of a corrupt Mussulman court*." How startling then in the light of the above facts is the following statement from the pen of the independent medical expert with the Opium Commission:—"The therapeutic effects of opium are much alike—tolerance apart—in all persons and in all climates, but it would seem as if only a select portion of the population were susceptible to its euphoric effects!" Let it be once again stated that the physiological effects of opium on the human organism—tolerance apart—are the same in India and Europe, and no Royal Commission will ever alter the facts which medical science has established upon the solid basis of practical experimental research and observation.

II. *Opium as a household remedy.*—As far as Bengal is concerned, SIR WILLIAM ROBERTS, in considering opium under this head, seems to have pinned his faith to Dr. CROMBIE of Calcutta, and we must therefore—to do him justice—give the quotation in full, upon which the opinion of the medical expert rests. Before doing so we quote one sentence to shew where the evidence he relies on comes from: "The testimony of some of the most experienced members of the Indian Medical Staff in regard to the value of opium as a domestic remedy, was impressive." Then after quoting Dr. BUCHANAN he gives the following most touching and convincing picture of Eastern Bengal

by Dr. CROMBIE: "I think it desirable," says Dr. CROMBIE "that the Commission should know something of the conditions of life obtaining in a place such as I have lived in for a great part of my service in India. I refer to Eastern Bengal (Dacca). There, when a man wants to build a house, he first of all digs a tank and with the earth from which he has dug the tank he raises a mound and on the top of that he places his house. The elevation of that mound depends entirely upon the height to which the annual floods rise. The floods rise with fair regularity, but sometimes they go two or three inches higher than the average, and then the inhabitants of those houses have to live on rafts inside their houses and their cattle are tethered up to their bellies in water. These people have generally no boats. They paddle about on rafts made of plantain trees and the boys go to school in what I call wash-hand basins. They are earthen *gumlas*. The boys squat at the bottom of the *gumla*, and paddle to school. This is the only means of communication. Some of those dwellings are extremely isolated. There may be only one household within four or five miles. There is no native doctor or dispensary within five or ten miles of them. I am convinced that to deprive these people of the possession of opium, except under medical advice, would be a terrible and wanton cruelty. It is the only medicine of any value that is available to them, and if you deprive them of it, I should not like to be one of those who do it." There were many strange and startling statements made before the Opium Commission, but we are not aware that there has been any more misleading and more mischievous statement than the above, made by a responsible medical officer of the Bengal Medical Service. SIR WILLIAM ROBERTS could have found out for himself whether the inference implied—but cautiously not stated—that opium was a household remedy in Eastern Bengal, was true or not by referring to Table I at the end of the Report, shewing the distribution by districts, of the opium habit in British India. We infer that Dr. CROMBIE was not theorising, or speaking beyond his own personal experience when he wrote the above, and his experience we understand, was almost entirely confined to the Dacca district; for he says: "I was for a long time Civil Surgeon of Dacca, but for only seven years of that period did I actually reside in Dacca. It will be observed that Dr. CROMBIE assumes that (1) the waterlogged ryots of Eastern Bengal were sorely in need of opium, and (2) every household possessed it as a household remedy, because of the malarious conditions under which they lived. It is very evident that if they possessed opium, its use must be to cure or ward off malaria. It will astonish SIR WILLIAM ROBERTS to learn that of all the districts of Eastern Bengal, Dacca and Myensing have the least average consumption per head per annum. The mere fact that Dr. CROMBIE mentioned the circumstances, and inferred that opium was a household remedy in Eastern Bengal, was enough. No further investigation was necessary. His statements must be true! We admit the conditions described in Eastern Bengal point to an intensely malarious region; but we deny that opium is even known as a prophylactic, much less used as a household remedy among the ryots of Eastern Bengal. We challenge Dr. CROMBIE to prove or even to assert in the presence of competent medical men who know Eastern Bengal, that opium is used by the ryots as a household remedy. The statistics

point all the other way. We have the following figures in the Opium Commission's Report, which prove that of all the districts of Eastern Bengal, Dacca and Mymensing have the lowest consumption of opium—5.1 and 5.8 grains per head per annum respectively. The following undoubtedly malarious districts have all a low average:—

| Yearly average consumption of licit opium per head. | | | |
|--------------------------------------------------------|-----|-----|--------------|
| Murshidabad ... | ... | ... | 23.5 grains. |
| Burdwan ... | ... | ... | 22.8 " |
| Rungpur ... | ... | ... | 20.6 " |
| Dinajpur ... | ... | ... | 14.4 " |
| Rajshahi ... | ... | ... | 13.8 " |
| Naddea ... | ... | ... | 10.9 " |
| Mymensing ... | ... | ... | 5.8 " |
| Dacca ... | ... | ... | 5.1 " |

In the first six districts in the above list, malaria prevails, but if we would represent them in the order of malarial intensity, we must reverse the list and begin with Naddea, Rajshahi, Dinajpur, Rungpur, Burdwan, and Murshidabad. In these districts, some of which we know intimately, we are absolutely certain that opium is *never used either as a prophylactic or as a cure for fever*. How then does it come to pass that where Dr. CHROMBIE tells us it is a household remedy, the consumption should be less than in those intensely malarious districts, where it is *not used either as a household remedy or as a prophylactic against malaria*? We must remember that these averages do not mean what they say. To shew the utter absurdity of the average consumption, as applied to Eastern Bengal, we proceed as follows: On the authority of SIR WILLIAM ROBERTS we know that "among the easier classes the daily allowance frequently runs up to 20 and 40 grains and sometimes far beyond this." Let us take an average of 33 grains per day for well-to-do men who take opium in the Dacca District. In one year, one such consumer would use 10,950 grains. This would be equal to 2190—5-grain-consumers; and if we divide these 2190—5-grain consumers into the population (2,420,656) we have 1,106 consumers of 30 grains per day, consuming the whole of the opium sold in the district of Dacca— $1106 \times 30 \times 365 \times 12,110 \times 700$ grains or say 12,100,000 grains in round numbers. But Dacca has six large towns with an aggregate population of about 11,000. We find that well-to-do opium eaters are found chiefly in these towns; and no one would charge us with defaming their fair name for moderation in the use of the drug, if we distributed these 1,106 opium consumers among that urban population. Thus we see that the whole of the opium used in Dacca is consumed by a few moderate well-to-do consumers, who are scattered chiefly in Dacca itself, and the five smaller towns throughout the district.

We could not ask SIR WILLIAM ROBERTS, and Dr. CHROMBIE his most reliable medical authority, where the ryots of Dacca are to obtain their opium? Not from illicit traffic in the drug, for it does not exist there to any appreciable extent; not from Government licensed shops, which do not exist outside the towns, and have only sufficient opium to supply 1106 moderate consumers who are well-to-do, scattered in the city of Dacca, and the five larger towns. Thus we see that the "wanian crutch" threatening the Eastern Bengal ryot is not that he will be deprived of his opium, but that

he has never been adequately supplied with it, and has never taught to use it, under any of the distasteful conditions that constitute his hard lot.

From whatever point of view we look at the evidence tendered by Dr. CHROMBIE to the Opium Commission, we are struck with amazement at its audacious inaccuracy. The abnormally low average consumption of 5.1 grains per head per annum in Dacca, when compared with 747.4 grains in some districts in Assam might have caused him to hesitate before he committed himself vaguely to inferences which he might have known were grossly misleading. We know the cause of the excessive consumption in Assam viz., the legacy left by opium cultivation, but why is the average in Dacca so low, if it is so intensely malarious and opium is used as a household remedy there? The answer, as we have shewn above, is plain—the statement cannot be true of Dacca, nor is it true of any district in Bengal.

III. Opium as a remedy and prophylactic against malaria.

That Sir WILLIAM ROBERTS was supplied by some of the official witnesses, with evidence that, to say the least, did not tend to lead him to clear views of the opium habit in relation to malaria, the following extracts will prove:—He says "*The evidence laid before the Commission showed that in some districts of India the local consumption of opium bore a close relationship to the greater or less prevalence of malaria in the localities*," and as proof of this he quotes in a foot-note the following:—"A striking illustration of this was given by Mr. WACE, Commissioner of Patna Division. He stated: 'The effect of climate in regulating the use of opium is curiously illustrated in the district I know best, viz., Bhagalpur. The district is cut in halves by the Ganges. The southern part is dry and healthy, the eastern half of the northern part is damp and malarious, especially where it borders the Kosi River. The three most malarious thanas—Kishen gange, Mudhupur and Partang, with a population of 27 per cent of the whole district, have 42 per cent. of the opium shops licensed for the whole district. The three driest thanas of the south containing a population of about $\frac{1}{3}$ of the damper thanas have only two opium shops, while the three damp thanas have seventeen. We find on enquiry that in the sub-division of Bhagalpur, south of the Ganges, where Mr. WACE says only two opium shops were required on account of its healthiness, that for upwards of twenty years opium cultivation has been carried on there and in the adjoining district of Monghyr.'

Whether southern Bhagalpur is healthy or unhealthy has nothing to do with the prevalence of the opium habit there. The people of that sub-division are largely given to the use of opium, but as they cultivate it themselves and as their neighbours—the ryots of Monghyr—do the same, it would have been useless to plant opium shops among them. Yet this is the kind of evidence upon which SIR WILLIAM ROBERTS relies for upholding the theory that opium bears a "*close relationship to the greater or less prevalence of malaria in the localities*."

It is not creditable that the medical expert on the Opium Commission should have allowed himself to be so completely under the influence of Government officials as to state that "*in this general sense there was a consensus of (official) opinion that opium was an indispensable medicine*."

of the prophylaxis against the prevailing complaint (malarious fever) of the people of India." It is vain to point out that the consumption and distribution of opium throughout India bear no definite relation whatever to the existence even, far less the intensity, of malarial fevers in different parts of India. Thus we find Darjeeling with a consumption of 15.7 grains per head per annum has no malaria, while Jalpaiguri, including the deadly feverish Dooars, has only 6 grains. Balasore in Orissa—the seat of previous opium cultivation—considered one of the healthiest districts in Bengal, shows a consumption of 88 grains per head, while the terrible swamps of Eastern Bengal (as described by DR. CAMMERMEYER, viz., Dacca and Mymensingh together consume only 5.4 grains per head. Simla with a small poppy cultivation—which should reduce the average considerably—far above the malarious zone, shows a consumption of 136 grains per head, while Dinajpur and Rajshahi, the two most malarious districts in Bengal, show together only 1.38. These figures show clearly that malaria has absolutely nothing to do with the prevalence and distribution of the opium habit: indeed, as we have already shown, two thousand well-to-do opium eaters would account for all the opium consumed in any one of the malarious districts we have mentioned; and we should find them all scattered in towns where opium shops only exist.

That these anomalies in the distribution and consumption of opium in the districts of India escaped the keen observation of the medical expert we do not assert; but that they would not fit into his malarial theory he clearly perceived from the beginning, and hence we have the new "euphoric" quality and marvellously-developed physiological instincts, by which whole races—"select portions of the population"—found that they were susceptible to the "euphoric effects" of opium!

To support the anti-malarial theory, which neither facts nor figures would lead themselves to, SIR WILLIAM ROBERTS revives old and discredited views of opium in which it was found that opium contained "narcotine" which he credits with distinct "antiperiodic properties," of which Patna opium contains 6.36 per cent. It would therefore require 16 grains of crude opium to equalise the minimum dose, 1 grain of narcotine, which was found effective in arresting the paroxysms of intermittent fever, and 48 grains to equalise the maximum dose. From these calculations* it may be inferred that only large consumers of opium would be absolutely protected against the malarial poison.....During an attack of ague, quinine is given in doses of five to ten grains; but a dose of two grains taken daily is held to be effective as a prophylactic against recurrent attacks. The same rule probably holds good as regards opium and its alkaloid narcotine. On this view it may be assumed that moderate consumers of opium, although not rendered absolutely immune against the malarial poison, would be more or less protected from recurrent attacks,—and if the attacks returned they would return less frequently and with mitigated severity. These particulars I think, adequately explain why opium-eaters are not altogether exempt from malarial fevers. The smaller consumers either lack the means or they lack the tolerance which

would enable them to take opium in sufficient quantity, to contain an efficient protective dose of narcotine.

The question was often mooted before the Commission why it was that, notwithstanding all this evidence in favour of opium in malaria, medical men in India do not prescribe opium for the cure and prevention of malarial fevers? The explanation is very simple in the light of the facts disclosed above. Opium contains morphia as well as narcotine. "This puts an absolute bar to the use of opium as a general antiperiodic. It could not be so used without the most serious risk of narcotic poisoning."

It is assumed in the above quotations that (1) moderate consumers of opium are protected against recurrent attacks of fever; and (2) that excessive consumers are rendered immune against the malarial poison. Both these statements every Indian physician knows to be without any foundation or truth. Opium-eaters enjoy no immunity from malarial fevers, nor are their attacks less frequent or less severe when they do occur. To obtain any benefit from the minute quantity of narcotine contained in opium a patient must at least take 16 grains in a dose to "be effective in arresting the paroxysms of intermittent fever," and probably at least 4 grains—a poisonous dose—to act as a mild prophylactic. Let a case be supposed. A patient has an attack of quotidian fever; he has had previous experience, not once but many times, that the fever cures itself or wears itself out in the system. We come and tell him of the antiperiodic properties of opium and assure him that although a $\frac{1}{4}$ grain dose—with which he must begin—will not arrest the paroxysms of fever, yet when he by daily practice acquires tolerance for 16 grains per day a few years hence, (if he can afford to buy that quantity), he will be protected. Or, if instead we tell him that 4 grains a day, which can be taken after 6 months' habitual eating, will not prevent you having fever; but the attacks, when they return, will "return less frequently or with mitigated severity." Would that dim prospect of cure even if it were true, (which it is not), induce the fever-stricken ryot to begin opium? Again we are informed that morphia in opium "puts an absolute bar to the use of opium as a general antiperiodic." "It could not be so used without the most serious risk of narcotic poisoning." If morphia contained in opium "puts an absolute bar to the use of opium as a general antiperiodic" in the hands, of skilled medical men, how is it so safe, so efficient, and so highly commended when left in the hands of ignorant natives of India? And if physicians never prescribe it for malarial fevers, how have the people, who do not see it, found out its antiperiodic properties? One does not know which to admire most: the lack of reliable information regarding the Bengal ryot and his habits for which he is not to be blamed, shown by SIR WILLIAM ROBERTS, or the ingenuous confidence with which he elaborated an illusive theory, which, a visit to any malarious village in Bengal with a non-official interpreter would dispel for ever.

The first of the new buildings included in the scheme for reconstructing the Calcutta Medical College is well in hand and making rapid progress. It is to be for the Anatomical Professors' Department, and will consist of a large and suitable dissecting room and lecture theatre.

HOW TWO PRESIDENCY SURGEONS COUNTERSIGNED A PRIVATE PHYSI- CIAN'S CERTIFICATE.

JUDAS, ON MEDICO, as his veiled personality preferred to shrink itself behind, said in his letter to the lay press, that the signing of medical certificates with private physicians was "simply a matter of fees."

Now we are not inclined to retort by reiterating such a charge against the other side; for we feel that any such insinuation of dishonesty, whether levelled at official or non-official physicians, would fall to the ground as a base and cowardly libel.

It is however extremely ill-advised and ill-timed for MEDICO, or the officials who have used this cringing sycophant as a cat's paw, to have aired this question of the counter-signature of independent medical certificates by Presidency Surgeons. The scathing and wrathful denunciations of MR. JUSTICE NORRIS against official methods of signing medical certificates, are still ringing in the ears of the public, and surely the effort to bolster up such an egregious anomaly is as unwarrantable as it is ludicrous.

But there is an ethical aspect to this question of compelling the servants of Government, who are sick and under the care of private physicians, to have the certificates of their family doctor countersigned or endorsed by a Presidency Surgeon, and it is this. A Presidency Surgeon may have a grudge against a practising physician, and when his medical certificate is brought to him for endorsement by a patient, he either refuses to sign it, or places upon it some remark which both nullifies the intention of the certifier and at the same time discredits not only the practitioner's ability as a physician but his veracity as a man. To say that all Presidency Surgeons would be guilty of such meanness would be a cruel and unjustifiable slander, but that there are "exceptions," the following story only too truly reveals. Here is the story:—

A Government official was for some time under the treatment of a private practitioner, and very little improvement resulting, the patient was taken to hospital and after a few weeks was discharged, somewhat improved in health. Shortly after, his strength seemed to be very markedly lowered, and it was thought advisable to send him for a change. A medical certificate to this effect was granted by his family doctor to enable him to apply to Government for leave.

Here is a verbatim copy of the certificate:—

"Certified that Mr. _____ is suffering from material fever and anæmia, and that he is unable to attend work for three months. Mr. _____'s health is greatly impaired and he requires rest and a change to ensure recovery.

(Signed) _____ M.D.

Calcutta, _____

The following note was scratched across this certificate by the countersigning Presidency Surgeon:—

"Fourteen days will be sufficient if he is properly treated.

(Signed) _____

Surgeon-Lieutenant-Colonel.

This endorsement is so extraordinary and so remarkable that it is well to record the patient's own statement

regarding it. He said: "I took the certificate to Dr. _____. He read it, shuffled about in his seat, looked very angry, did not feel my pulses nor ask me any questions about my health, but scratched the remark across the certificate and gave it to me. As I left the office, Dr. _____ called me back, took the certificate from me and scored out the word "properly" and then returned it to me." The patient finding the certificate practically nullified by Dr. _____'s remark on it, brought it back to his family doctor, who re-wrote it and told his patient to go to any other Presidency Surgeon he pleased. He did so, and this second officer, after carefully examining the patient, countersigned the certificate, accepting the family physician's recommendation that the patient needed and should get three months' sick leave, and what is more he got it. Be it noted that the certificate was countersigned by the second Presidency Surgeon within twenty-four hours of the first man's remarkable judgment by *instinctive intuition, not by examination*. There can be no two opinions about the conduct of Presidency Surgeon No. 1. It is a case of personal feeling and vindictiveness. We have abundant evidence of a documentary kind to prove this charge. We have before us the original certificate with that remarkably unprofessional remark on it. Clearly this "officer and a gentleman" prostituted his official position to vent his private animosity against a brother professional, and such conduct cannot be too widely exposed, nor too strongly condemned. It shews forth the unenviable position in which private physicians are placed in their professional relations with their official brethren, and emphasises the immediate and imperative necessity that exists for the Government to rescind the rule which compels the countersignature of independent certificates by State practitioners. The Government has a powerful weapon in its hands to prevent the mis-use of their rights and privileges by independent physicians in simply ruling that any practitioner discovered in the crime of granting a false certificate, shall be publicly gazetted as debarred from the further granting of such certificates for all State purposes.

COMMENTS AND NEWS.

METHODS OF SLAUGHTER ABBATOIRS.

A METHOD of slaughter having three such important advantages as (1) the infliction of the least possible pain, (2) of being hygienic, and (3) of being economical must commend itself to the very favorable consideration of consumers of animal food. We find from the *Birmingham Medical Review* that DR. DEMBO'S investigations lead him to the conclusion that of all methods in vogue, the Jewish method of slaughter is the only one in which all these advantages are combined. As to the first of these advantages in the Jewish method, the carotid arteries being directly opened by a cut with a sharp knife, a very large volume of blood is at once poured forth; the supply to the brain is almost completely stopped; there is an extremely rapid fall of blood-pressure, and consciousness is wholly and invariably lost in from three to five seconds. By no other method now in use is there less pain caused in cutting through the sensitive structures of the neck. The method of slaughter adopted in places where the blood is collected for the manufacture of albumen, is transfixion of the neck with a

State of danger, leaving the weapon in the wound. Death is slow, in transition and cutting through the soft substances, as adopted in England, the large arteries are less efficiently opened than by the Jewish mode. In the neck-stab method adopted in Russia, Germany and other countries, the knife is thrust between the occipital bone and the first cervical vertebra and the spinal cord completely severed; but Dr. DEMEO finds that the medulla is not destroyed in the thrust, and the animal remains fully conscious, while the further operations are being performed. The method of stunning cattle with a mallet or polcaze, then making a hole in the skull and destroying the medulla, and subsequently opening the carotids, is the most prolonged of all methods. Moreover, it is an exception to find an animal stunned by a single blow, five or six blows being required on an average, and twelve minutes may elapse before unconsciousness is produced.

The hygienic advantage is that by the Jewish method the vessels being most completely drained of their blood the meat is less prone to decomposition. In all the other methods there is produced a greater or less degree of vasomotor paralysis, and for this reason materially less blood escapes. Furthermore in the Jewish method *rigor mortis* begins in less than half the time required in other processes and lasts longer by several days, and the early onset and long duration of *rigor mortis* is stated to be essential for the provision of wholesome meat.

The economic advantage of the method lies in the fact that the blood-vessels being most completely emptied, the weight of the meat is diminished.

ANTI-VENENE: IMMUNITY TO SNAKE-BITE.

AFTER six years' hard work and numberless experiments on cats, grass-snakes, guinea-pigs, a horse, rabbits and white rats, with the poison obtained from the most venomous snakes of Africa, America, Australia and India, with a view to establish or break down the hypothesis of "producing by successive inoculations a degree of resistance against the toxic effects of snake-poisons," Professor THOMAS R. FRASER, M. D., informed the Royal Society of Edinburgh that his investigations had clearly proved that beginning with a trifle below the minimum lethal dose and gradually increasing the quantity of the toxic substance at each inoculation, an animal could be rendered proof (immune) against the poisonous effect of venom sufficient to kill fifty non-protected animals of the same size, and that the blood-serum of animals thus protected against large lethal doses of venom was able, when injected into them, perfectly to prevent lethal doses of the most poisonous of serpents from producing death in non-protected animals. To this serum he applies the name of *Anti-Venene*, and claims an equal result from it, whether in solution, natural, or dried in *vacuo* and then dissolved in water. The snakes with whose venom he made his experiments were:—*Crotalus adamanteus*, *C. durissus*, *C. horridus*, (the most venomous of the rattlesnake tribe), *Dinemia superciliosa* (the brown snake), *Naja tripudians* (cobra-di-capello (India) *Trigonoccephalus contortrix* (the copper-head), *Vipera arctians* (puff-adder), *Aspidelaps lubricus* (the night adder), *Naja haiti* (yellow cobra or Olopatra's asp), *Sepeidon hermaphrodites* (Ringi Hais Slang or Kinkas) *Pseudochis purphyriacus* (Australian black snake), and *Vipera cerastes* (vipers). All of which are the most deadly of all the known poisonous serpents; but as in their natural states the venoms are in constant inactivity, owing to the various quantities of water they contain, constancy in experiment was obtained by drying them in *vacuo* over sulphuric acid, and then dissolving a weighed quantity of the impalpable substance in distilled water for the inoculations. Though the results so far obtain-

ed have been highly satisfactory with the brute creation, still, further experiments have to be made with a view to their effect in man and also to discover the real constituents by which the antidotal effects were produced, and this because there are and must be limits to this curative power dependent on (a) the susceptibility and idiosyncrasy of the person bitten, (b) the quantity of the poison injected by the bite and taken up into the system, (c) the special antidotal activity of the *Anti-Venene* that is used, and (d) the duration of the time during which the toxin has had an opportunity of exerting its poisonous action before the *Anti-Venene* is administered.

HAVE YOU BROUGHT MY FEE?

It is said of a certain Calcutta Professor of Midwifery, whom India's great comic vocalist, DAVE CARROW, styled "The Deliverer of Bengal," that whenever he was asked to see a patient, his first question was, "have you brought my fee?"

Dr. B. JONES of Leigh, writing to the *British Medical Journal*, apropos the above subject, says:—

"Many years ago a certain man went from Jerusalem to Jericho, and happened with disasters that are, I hope, well known to all of us, and certain religious professors who found him half dead on the road, passed by on the other side. But one good Samaritan took him to an inn and paid the charges of the landlord for looking after him—in advance

"Now-a-days the Priest and the Levite would have run, if convenient, to the nearest doctor and requested him to be the Good Samaritan, and would probably vilify him, either publicly or privately, or both, if he did not at once drive off to the accident, whatever other claims he might have upon him at the time. The greater the profession of benevolence, the greater the horror at the request of the doctor for that 'tuppence.'

"I doubt not that most members of our profession, indeed all, do their neighbourly duty as well and as frequently as any other member of the community. The rub comes in where we are expected to act vicariously for anyone who chooses to call upon us for this purpose. To such we may very well say, 'Where is your tuppence?' I make it a rule never to pay any attention to casual messages or urgency calls unless to my own patients, or when given by some one who is prepared to pay my fee.

"If we would only assert ourselves a little more, and let people understand that we must be paid for our services the same as any other profession, the less difficulty there would be in obtaining our rights. We have done so much gratuitously in the past, that people forget we have our bills, rent, rates, and taxes to meet the same as others. In cases of emergency, calls by police, or anyone else, a good working policy is to ask, 'Where is the tuppence?'

THE TREATMENT OF MALIGNANT GROWTHS BY TOXINES.

Dr. WILLIAM COLEY has continued to prosecute his investigations of the treatment of inoperable malignant tumours with erysipelas toxins. The method of treatment has now been improved by using the serum of the horse rendered immune to erysipelas. This does away with the severe reactions and depressing effects that follow the injection of the toxins, but the relative value of the serum and of the toxins has yet to be determined. His successes may be tabulated thus: In one case of recurrent carcinoma of the breast treated with the toxins for several weeks, the growth was evidently checked, though there was no decrease in size. Five minim injections of the erysipelas serum given for two weeks had no apparent effect on the tumor. The second case was one of the largest carcinomas ever seen by the doctor, and which was

proved to be a continuous by microscopic examination. The serum injections were employed and improved method in a few days. The injections were kept up for several weeks and the improvement continued. Toxins were then substituted for the serum to note comparative efficacy. The tumour shrank in size. Large doses were then employed and a mass of tumour tissue of considerable size sloughed away, and in the next three months was reduced to one-half its original size.

Case No. XI (carcinoma of neck and sternum) under treatment with the serum: tumour slightly decreasing in size. Case IV.—Rapidly growing epithelioma of lower jaw treated with the mixed toxins of erysipelas and bacillus pyridiglossa injected into the chin every 24 or 48 hours. The ulcer entirely healed in three weeks. Seen nearly eight months later; there was no evidence of the cancer remaining and the skin had regained almost a normal appearance.

Professors RUDOLPH EMMERICH and HERMAN N. SCHOLL, M.D., have also been experimenting on the cure of cancer with erysipelas serum. These gentlemen find that the serum from inoculated sheep is more powerful than that of other animals. The results of their experiments in a number of cases lead them to say that "we possess in erysipelas serum a specific for cancer."

THE PLACE OF BACTERIOLOGY IN PRACTICAL MEDICINE.

ADVERTING on the rather heavy mortality in the Brisbane Hospital for sick children, DR. A. J. TURNER complains that over one-third (i.e., 308 out of 2,314 cases) of the cases treated and nearly two-thirds (i.e., 201 out of 939) of the deaths were due to the invasion of specific bacteria, such as staphylococcus and streptococcus pyogenes, which accounted for the following deaths:—pneumonia 25, typhoid 7, diphtheria 120, tetanus 3, tuberculosis 20, or a total of 201, of which considerably more than a half was due to the encroachments of the bacillus diphtheria, of which he observes that as membranous tonsillitis has sometimes been mistaken for true diphtheria, which latter cannot easily be diagnosed in its early stages as to whether the impending disease may be mild or virulent diphtheria, or any other form of bacillary disease, many of whose attenuated varieties are serologically indistinguishable from the virulent form. We know practically nothing as to why it should be so; but we do know that there is an essential similarity of all bacterial poisoning and of its dependence on chemical bodies termed toxins; while a large number of pathogenic bacteria produce within the diseased animal body an antitoxin which is specific and capable of neutralising the toxin that excited its formation; but neither acts on nor kills the bacilli themselves. If a healthy animal be carefully injected with a toxin, the dose of which is gradually increased at each injection, a stage will be reached when the animal becomes refractory or immune to large doses of toxin, which at an early stage of the attack (or experiment) would have certainly proved fatal. And in the blood of the artificially immunised animal will be found a body (i.e., anti-toxin) capable of destroying, neutralising or in some way rendering harmless, the specific toxin produced by the bacillus in natural attacks of the specific disease in other animals. But to be of positive value in successful treatment the gravity of the case must not be dependent on conditions, such as tubercular pneumonia, which are due to secondary affections, and are not affected by the antitoxin, which should be given as early as is possible, and in full and large doses, while there should be no hesitancy, to resort to tracheotomy or tracheostomy to relieve respiratory obstruction, if be present. Though life may be saved and cures effected,

and the immunity produced by the antitoxin is only temporary, surely lasting for months, and disappearing as the antitoxin is excreted from the system.

MEDICAL AND SURGICAL WORK DONE IN DHOROJI, GONDAL STATE, KATTYAWAR.

DR. MULSHANKAR DAMODAR sends us the following statement of work done at the Sir JAMES FRASER'S Hospital, Dhoroji, during the first decade of His Highness' regime from 1884-85 to 1893-94.

Patients Treated.

| Years. | Males. | Females. | Children. | Total. |
|---------|--------|----------|-----------|--------|
| 1884-85 | 6,724 | 2,504 | 5,477 | 14,705 |
| 1885-86 | 7,188 | 3,060 | 6,439 | 16,687 |
| 1886-87 | 7,634 | 3,538 | 7,324 | 18,496 |
| 1887-88 | 8,423 | 4,270 | 8,197 | 20,892 |
| 1888-89 | 7,298 | 3,718 | 7,781 | 18,797 |
| 1889-90 | 7,984 | 3,858 | 7,948 | 19,735 |
| 1890-91 | 8,264 | 4,141 | 8,016 | 20,421 |
| 1891-92 | 8,484 | 4,687 | 9,121 | 22,292 |
| 1892-93 | 8,423 | 4,592 | 8,647 | 21,662 |
| 1893-94 | 9,201 | 5,040 | 8,856 | 23,097 |

Surgical Operations Performed.

| Years. | Major. | Minor. | Total. |
|---------|--------|--------|--------|
| 1884-85 | 49 | 361 | 410 |
| 1885-86 | 73 | 494 | 567 |
| 1886-87 | 20 | 639 | 709 |
| 1887-88 | 40 | 640 | 680 |
| 1888-89 | 29 | 590 | 619 |
| 1889-90 | 32 | 649 | 681 |
| 1890-91 | 45 | 578 | 623 |
| 1891-92 | 64 | 661 | 725 |
| 1892-93 | 54 | 697 | 751 |
| 1893-94 | 58 | 836 | 894 |

During the first quinquennium the hospital was in charge of DR. HARI BHICAJI NAIK, and during the second, in charge of DR. MULSHANKAR DAMODAR TRINEDI.

NOTHING NEW UNDER THE SUN.

DR. H. B. EVANS, writing to the *Medical World*, makes the following quotations:—

Subcutaneous Injection in 1604.—"Went with MR. PIERCE, the surgeon, to see an experiment of killing a dog, by letting opium into his hind leg. He and DR. CLARKS did fail mightily in hitting the vein, and in effect did not do the business after many trials; but with the little they got in, the dog did presently fall asleep, and so lay till we cut him up."—Pepys's Diary, Vol. II., p. 126.

Aqua.—There cannot be any doubt as to the advantage of boiling suspected water before using it. This was well known to the ancients. HERODOTUS, writing of a period about 550 B.C., states that the King, when on campaign, was supplied with abundance of water from the river Chaspeus, previously boiled, and stored in silver vessels.

Removal of the Vermiform Appendix.—MR. BRADLEY of Manchester, in operating for the relief of a strangulated inguinal hernia, found the vermiform appendix lying in the opening, perfectly black and apparently lifeless, and accordingly removed it by means of a catgut ligature. At the end of a week, the patient appeared tolerably well, but imprudent eating induced severe vomiting, and he eventually died from exhaustion.—*British Medical Journal*.

In 1617 FABRICIUS used metal wire for bone-sets.

In 1646 PROF. BRUNSON used silver wire for animals, before DR. BINE graduated.

STATISTICAL VALUE OF DEATH-RATE.

Death statistics are always misleading. To be of any statistical value, they should be worked out with due consideration to local conditions. DR. MAJOSLM MORRIS makes some very valuable remarks in the *Practitioner* on the manner of arriving at death-rates. A high death-rate in a place may not mean local unhealthiness; and unwarily, circumstances may make the death-rate of a healthy locality compare unfavorably with that of a place less healthy. For instance, the tendency to death is greatest at the extremes of life, and the female death-rate is generally lower than the male. In considering therefore the ratio of deaths to population, due allowance should be made for local peculiarities in age and sex distribution. Again it is unfair to charge the healthiness of a town having a work-house, an asylum and several hospitals with all the deaths occurring in that town. It is the unhealthiness of the outlying places to which, perhaps, is to be correctly attributed, much of the mental and physical ailments which have swelled the death-rate of the town, and it would be misleading to include all the deaths occurring in its charitable institutions, in the death-rate of the town itself. Callings and occupations of the inhabitants moreover, influence the death-rate of a place; and as weekly, monthly, quarterly and annual rates vary with the season, epidemic prevalence, etc., decennial rates should be considered in gauging local healthiness or otherwise.

PATIENT FLOCHING.

SAYS the *Medical Times and Hospital Gazette*:—"The ethics of the profession are being gradually broken down and scattered to the winds, especially the laws which are supposed to govern the relations of medical men in regard to visiting each other's patients. Some physicians or surgeons holding a public appointment as medical officer of health, surgeon to the police, physician or surgeon to a railway, bank, or insurance office, seem to regard themselves as above all ethical laws limiting their action in regard to the patients of other medical men: although such a one is the first to cry out if another doctor is called upon to visit one of his private patients. He readily pays 'surprise' visits to the patients of other doctors, and reports thereon without a word of apology. Recently the London School Board decided to appoint medical men to visit and examine children whose parents send medical certificates stating their unfitness to attend school. One would think that it would be difficult to get medical men to undertake such work. Not so, however: the appointments are eagerly sought after, and it is said that the official doctors to the Board detect a large number of cases in which the medical certificates do not accurately describe the actual state of the patient."

Does this paragraph smite the consciences of some official patient floggers in Calcutta?

THE CLINICAL THERMOMETER IN THE DETECTION OF THE FIRST SYMPTOMS OF PULMONARY TUBERCULOSIS.

As in the "incubation" or, as some folks erroneously term it, the "pre-tubercular stage," when tubercular nodules are just beginning to form, it is next to impossible to examine the expectoration microscopically for confirmation or indication of this affection, because it is more than possible that the patient may spit up catarrhal discharge and thus provide correct diagnosis and line of treatment of the disease in its embryonic state, and thus prevent tubercular involvement. DR. C. W. HERNIMAN notes that the ordinary *bulb thermometer* affords the quickest and surest index to tubercular infiltration, as a rise of temperature of from 1°F to

1.5°F at some period of greater or less duration, every 30 days during a fortnight of close observation may, when associated with loss of weight and vitality, be safely regarded as the first symptom of pulmonary tuberculosis, even though there has been no accompanying cough and expectoration and though physical examination gives negative results. He therefore advises to guard against the accident of wrongful diagnosis by watching the temperature record of the patient for a period of two weeks, during which all habits of accidental elevation are eliminated and the patient instructed not to carry his exercise or occupation to the extent of physical fatigue during the "temperature test."

SANITATION IN BURMA.

In his general remarks, DR. SINCLAIR draws attention to some of the insanitary conditions which tend to increase the mortality. Among the Burmese there is, generally speaking, no rational idea about sick-nursing, and practically no suitable diet for the sick. The average Burman has a decided aversion to milk, assigned to his desire not to rob the calf of its proper food. When prevailed on to accept this best of all diets for the sick, he prefers the milk of the goat to that of the cow. He objects also to eggs. Then his clothing is generally insufficient, especially in the rains and cold weather, while children run about naked at all periods of the year. Fevers and bowel complaints are a natural consequence. Among insanitary habits requiring correction, DR. SINCLAIR includes not weaning children till about the age of two. There is no doubt that the mortality among Burmese children is very high, and the wonder is that it is not even higher, seeing that so many Burmese houses are situated in swamps, and that the children are never properly clad or fed.

THE USES OF MEDICAL SOCIETIES.

DR. X. C. SCOTT, of Cleveland, O., in his presidential address said: "All medical associations, should be carried on for the purpose of elevating the profession and producing a beneficial influence upon its members, and also that they may meet face to face and thus learn to know each other personally and better. They should elevate personal character, afford protection to professional interests, and advance personal attainments. To be successful the financial affairs of the association should be conducted with the same careful and rigid supervision that pertains to any private business. He thought the idea of reading all papers before the general body, would afford larger audiences, create better and more interesting discussions, and consequently result in greater good to the majority of the members.

DOCTORS AND THEIR BUSINESS HABITS.

THE *Medical Bulletin* thinks that the success or failure of a medical practitioner to gain a fair competence depends on his business habits. To make and to save money, our contemporary thinks that the more exact and methodical a physician is in the handling of his accounts, both as to charges and collections, the more will his professional abilities be respected. It is therefore advisable that a physician make his worth felt by the public in charging only good fees for his services, and in carefully attending to the collection of his accounts. As one's practice is generally among those in moderate circumstances, or among the poor, the instalment system of collection is advised. In large towns this may be effected through a collector working on percentage, and in a small country village this may be attended to by the doctor himself.

DR. GEORGE KING, F.R.S.

In reviewing Dr. KING's report of the Calcutta Royal Botanical Garden on behalf of the Bengal Government,

MR. H. H. RILEY writes:—"DR. KING's singular talent for landscape gardening has enabled him, during the 24 years he has been in charge, to add greatly to the beauty of the garden by skilful grouping of trees and shrubs, and it now ranks high among similar institutions for picturesque scenery, no less than for scientific completeness. Within the past year he has laid the public under a further obligation by bringing out a guide to the garden, the want of which had long been felt."

SUCCESSFUL ACTION FOR MALPRACTICE.

AN action was recently brought against a surgeon of New York for negligence and unskillfulness in the treatment of a case. The witnesses for the defence showed that the surgeon was generally reputed and was professionally highly skilled. The plaintiff dwelt simply on the question of the degree of skill shown in the treatment of the case which gave rise to the action against the defendant. A verdict was given for the plaintiff, and was upheld on appeal, as it was held that the general character and repute of a surgeon does not affect the question of neglect of or malpractice in a particular case.

DEATH OF SURGEON COLONEL J. M. COATES, M. D.

It will come as a very sad surprise to hundreds of our readers to learn of the sudden death of DR. JOHN MARTIN COATES. He succumbed to an attack of cholera on the 10th July 1895. Few men were so universally loved as DR. COATES, and his death casts a gloom over many grateful hearts.

THE HOBBY OF COUNTERSIGNING CERTIFICATES.

The *Darjeeling News*, referring to the recent correspondence about Presidency Surgeons countersigning the medical certificates of private physicians, after condemning the practice, says:—"There is no test for qualification, but only a personal test, the accident of a doctor being a Presidency Surgeon. If a test of qualification were laid down to entitle a man to sign a medical certificate, that would be another matter. But this is not the case, and how are we to know that the Presidency Surgeon, who countersigns, is a better man than the doctor who signs?"

SHORT ITEMS.

We are very pleased to learn on enquiry that Surgeon-Colonel Cuffe, C. B., Army Medical Staff, whose death was announced in some of the home papers a short time ago, is enjoying most excellent health, in that beautiful Central Provinces Sanitarium, Pachmar.

A Parisian ophthalmologist says that the incandescent electric light is the least harmful to the eyes of all artificial light. Next comes the light of a good kerosine lamp, after that candles, and the worst of all is ordinary gas-light.

Surgeon-Captain H. C. Hodgkins, M.A.S., of the Calcutta Medical College, is gazetted to the rank of Surgeon-Major. We congratulate Surgeon-Major Hodgkins on this well-deserved honor paid to him by the State.

Dr. Evans, attached to the 20th Bombay Infantry, met with a severe accident on the 24th June, when out with the Nussirabad hounds, breaking his left arm and sustaining a severe shaking.

Dr. P. Hahir met with a carriage accident on the 28th June. He was driving and the dog-cart overturned and threw him out. It is gratifying to learn that, beyond a sound shaking, he has nothing serious to complain of in connection with the mishap.

The *British Medical Journal* says:—"We do not consider it would be unprofessional for a physician or surgeon's name to appear at the top of his prescription paper; and, in view of the illegibility of many signatures, it would have distinct advantages. It is a common practice amongst members of another profession—that is, solicitors."

The Lee-Metford rifle is pronounced unfit as a weapon of warfare, as its stopping power is unsafe. Its bullet may pass through your enemy, but he advances all the same, onto you down though he may fall after finishing you.

Several cases of typhoid fever, which have occurred lately in Simla, are attributed by Dr. Cunningham to the sale of impure milk brought in from villages in the surrounding Native States.

We regret to announce the death of M. Verneuil, the *doyen* of French surgeons. He passed away in ripe old age, full of honors and surrounded by troops of admiring friends, having filled all the higher offices of his profession in Paris.

Dr. William Gilbert Grace, M.B.C.S., the Champion cricketer of England, is to have a national testimonial. What will English doctors in India give towards it? The *British Medical Journal* has opened a list. Send in your shilling.

The Legislature of Pennsylvania has decreed that the oath taken on the Bible by kissing the book, shall be dispensed with. The Governor of the State has indicated that he will approve of the enactments to that end.

In the recent Dublin case of wrong diagnosis, where Dr. Hadden was fined, an appeal has been lodged against the judgment. The medical profession in Great Britain supports Dr. Hadden.

"When a man's down, kick him and keep him down." This seems to be the policy that the authorities are adopting towards Surgeon-Major Clarence Smith, the hero of the phantom kiss case.

Surgeon-Major Henry John Carter, F.R.S., of the Bombay Service, died in England on the 4th May, aged 82 years. He was a well-known scientist.

Somebody says, and has put it in print, that more physicians commit suicide than the members of any other of the learned professions.

Answering a recent interviewer, Dr. Lillian Hamilton of Cabul, said she "doctored men and women equally." This marks a new era in Oriental social life.

A reference has been made to the Principal Medical Officer, Her Majesty's Forces in India, as to the desirability of adopting the Pasteur filter for British troops.

The Prussian Government expends over \$30,000 a year in support of the laboratories connected with the medical department of the University of Berlin.

The General Medical Council has granted £3,000 as its share in the cost of preparing the new British Pharmacopoeia.

A monument to Father Damien, the "apostle to the lepers," has been erected in Louvain, Belgium, where he was born.

In Sweden ten years of study is incumbent on every medical student.

Use black pins in surgical dressings; they will not rust and can be more readily seen.

OUR LONDON LETTER.

(From our own Correspondent.)

The first flash of medical news in one of the evening papers relates to a strange, though not unique, occurrence that has taken place at the Borough of Portsmouth Infectious Diseases Hospital, Milton. It appears that a young man suffering from scarlet fever was admitted to the institution. The patient, however, left the hospital early the next morning and returned home. He was eventually taken back by the authorities. Culpable negligence of the nursing staff must be our verdict on this scandalous matter.

In order to give our Indian readers some idea of how their fellow-students and practitioners are faring in the mother country, we must record first the death of a former well-known member of the Indian service, viz., HUGH FRANCIS CLARKE CLEGHORN, M.D., J.P., LL.D., F.R.S.E. He was born in Madras in 1820, educated at Edinburgh and St. Andrews Universities, was a pupil of the renowned Professor SYME and one of the house surgeons to Edinburgh Infirmary. He graduated in 1842 and returned to Madras in 1842, where 12 years later, he was appointed Professor of Botany, passing the most active years of life in the I. M. S. In 1855 he was busy organising a forest department, and then became Commissioner for the conservancy of forest trees, &c. In 1869 he retired from the Indian service; his labors in this department being officially acknowledged in terms most complimentary. On his return to Scotland he was *pro tem.* Professor of Botany at Glasgow. He settled at Strathvie, Fifeshire, giving himself up entirely to his favorite botanic pursuits. He became a member of the Edinburgh Botanical Society, a Fellow of the Linnean Society, and was President of the Royal Scottish Arboricultural Society.

Mrs. GRIMWOOD, well known in Indian circles as the heroine of Manipur, was married here in London to MR. ANDREW, paper millowner of Carshalton, Surrey.

The new Bill for the Registration of Midwives, *anent* which so much heated discussion has arisen in various professional coteries, is not of sufficient interest to Indian readers for us to enter upon a lengthy disquisition on it.

MR. H. HARBEN, M.P., has contributed £1,500 to the Dental Hospital in Leicester Square.

The Glasgow students have united to present a gold watch to DR. YULE MACKAY, their Professor of Embryology.

We are gratified to hear that MR. THOMAS SMITH, Senior Surgeon to St. Barts, has been made Surgeon Extraordinary to H. M. the Queen, in the room of the late Sir WILLIAM HAYORY, F.R.S., Bart. of glorious surgical fame.

One of our medical contemporaries accuses a pharmaceutical journal of tempting chemists to prescribe by printing a weekly column of select prescriptions for divers ailments. Male apothecaries are being opposed by a lady gynecologist, who has somewhat daringly affixed a brass plate (on which the word "Miss" is very prominent) to each of the house doors in a well-known Dublin Square.

DR. MACARTHY'S JOURNALING to our notice the dangers of morphine and its uses in gynecological practice. He

probably thinks to arrest the spread of morphinomania. This however is fostered by the chemist, and not the physician. DR. BROOKS has demonstrated the treatment of wounds by immersion in oxygen gas, and explained how he cured a case of poisoned wound and another of ulcers *arabica* by means of a rubber cap placed on the head and pumping in the gas, with marked success. Neurotrophic disorders, such as *springo myalis*, RAYHAUD'S disease, aoromegaly, &c. are coming in for a large share of medical attention. DR. HALL has exhibited an interesting case of actinomycosis fungoides. The patient being a man aged 52. He had complained of pain in his arms and legs two or three years back. A swelling, the size of a goose egg, appeared at the right hip, then one followed on the right elbow. Since this time the tumours have appeared on the feet, head and face, breaking down and discharging in about six months. In October 1894 he began to complain of sore-throat. Tumours can now be seen in the pharynx and on the arytenoid cartilages.

A case of *Filaria Loa*, a disease common in Calabar, has been shewn by Dr. A. ROBERTSON. It appears to be a common complaint among the negroes, but is rare among the white visitors to these parts.

Scarlatina Maligna has been met with lately in Battersea and South Lambeth, the death-rate being very high.

On consulting the Medical Register there appears to be an increase of 10,000 more practitioners holding British qualifications than there were 20 years ago.

A leading contemporary advises the use of *Salol* in scarlet fever with a strictly milk diet (*Quicoe*). The drug which is an active intestinal antiseptic, useful in pernicious anemia, dysentery, and even cholera, is best given in capsule or tabloid form; it is then absolutely tasteless and very active; the dose should be from 7½ grains to 30 grains daily according to age.

Mrs. ELEANORA I. FLEURY, M.D., R. U. I., gold medalist, has been appointed assistant physician to the Richmond Lunatic Asylum, Dublin. Mr. H. ALLINGHAM is now Assistant Surgeon to St. George's Hospital.

A case of chronic insanity, after every remedy failed, has been cured by *thyroid feeding*.

A fearful case of black witchcraft comes to us from Ireland, where a woman was boiled or roasted to death under the impression that she was "fly" or a witch of vicious predilections.

If report is correct, the grandest "old man" in medicine is DR. BONSY of Havre, who is stated to have practised in India. He is 103 years of age, and is still hale and hearty. Another, 105 years old, is MR. W. SALMON, J. P., D. L., of Penlayne Court, Glamorgan, S. W. He became M. R. C. S. in 1809.

MR. W. TOWERS SMITH, a specialist in Foods and Obesity, has passed away.

The Annual Meeting of the British Association will be held this year at Ipswich about September next. A small book on the preservation of health in the Far East has been published by DR. MEANS of the Church Missionary Society, which proves interesting, and contains some excellent diagrams on prophylaxis, &c.

Dr. R. W. FELKIN tell us "that with selected men, one might colonise even West or Central Africa;" but we cannot forbear from stating that this wide-spread and loose generalisation does not accord by any means with our own experience in West Central Africa.

Dental caries has been extremely prevalent here of late years, and seems on the increase.

The Chemical Society have awarded the Faraday Medal to LORD RAYLEIGH for his discovery of "Argon."

A new element, called "HELIUM," has aroused some attention in Chemical circles.

We are pleased to relate that SIR JOSEPH FAYRER has recovered from his late severe and protracted illness.

We are delighted to inform our readers that Mr. CHRISTOPHER HEATH has been elected President of the R.C.S., England.

There are now two Royal Commissions in working order: One on the aged poor, and the second on "Vaccination."

HARVEY's masterpiece "*Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*" has been reproduced in *facsimile* from the Frankfurt edition, published in 1628.

Numberless accidents with paraffin lamps continue to be reported in London.

SIR JOSEPH LISTER, F.R.S., has been welcomed at Marlborough House by the PRINCE OF WALES who presented him with "the Albert Medal" from the Society of Arts, in recognition of his services in Antiseptic Medicine.

Current Medical Literature.

MEDICINE.

Obstruction of the Bowel Tested by Electricity.

ALTHAUS reports a case of a man fifty-four years old, who for three months had suffered with obstinate constipation. At the time of coming under observation the bowels had not moved for ten days, and the abdomen was distended and tender. The appetite was lost, and a condition of collapse existed, with sunken face and small feeble pulse. The introduction of the long tube proved unavailing, and electric treatment was resorted to. An insulated sound, with a fine metallic end, was introduced into the rectum, and a moistened conductor applied to the abdominal parietes, chiefly in the region of the sigmoid flexure. Through this circuit a primary faradic current was passed, and its force gradually increased until the patient experienced a decided feeling of vibration in the bowel. In the course of the day a copious intestinal evacuation ensued, with wonderful relief to all the symptoms. During the next two days the bowels acted ten times, and in the course of a week the patient appeared quite well.

A second case, in a woman fifty-seven years old, is cited, in which a like result was obtained from similar treatment.—*Brit. Med. Journ.*

Bright's Disease without Albuminuria.

MASON, after referring to the recorded cases, relates three cases of unquestionable nephritis occurring in patients aged fifty-eight, nineteen, and fifty-nine years respectively. In the first case there never was albuminuria, while the

patient was under observation. In the second case a chlorotic girl was admitted with many of the symptoms of Bright's disease, and yet there was no albuminuria. Two years later she was readmitted, when albumin was present in the urine. In the third case the patient had been under treatment with Bright's disease and albuminuria. Later she was admitted with influenza. The albumin entirely disappeared, but the symptoms of Bright's disease persisted. The author draws attention to the fact that the quantity of albumin present may be of little prognostic importance, and he relates an illustrative case. Albuminuria is a feature of secondary importance in Bright's disease; it may occur in health, it may exist in large quantities in cases of Bright's disease with few symptoms, and it may be absent in uræmia. As DIEULAFOY says, the important thing in renal disease is not so much what passes out in the urine, as what remains behind in the body.—*Arch. Gén. de Méd.*

A Rare case of Stupor with Forced Feeding for nine Years.

GADELIUS had an interesting case under his care,—that of a tailor, aged 32 years, an assiduous workman, slow, taciturn, but amenable to reason. Insanity of persecution developed, the prominent symptoms being anxiety and insomnia, with neglect of his person and refusal to take food. When spoken to he invariably answered in an undertone, "Fine weather, to-day," and, later on, "I do not know." Forced feeding was carried on uninterruptedly, from April 24, 1883, to February 12, 1892, the body-weight increasing during this period from 46 to 73 kilogrammes (101 to 160 pounds). From April, 1883, to May, 1886, he remained in a condition of complete stupor and amnesia. The author considers the prodromic delirium as a quasi-paranoid psychosis in a degenerate subject, and regards the case as a psychosis of exhaustion, being practically a condition of syncope from beginning to end. On awakening from the stupor the patient had lost most of his former knowledge of things and places, but soon recovered it.—*Hygæia*.

Facial Paralysis.

THE conclusions drawn from the observation of eighty cases of facial paralysis by Dr. RUDOLPH HATSCHKE are: Among the eighty cases were ten in which more than one attack had occurred. Sometimes one side, sometimes both sides were affected, and more than once there were third attacks. There seemed to be no tendency for one sex to suffer more than the other, and there was no preference for one side of the face over the other. As a rule, the later attack was more severe, but not invariably so. Two of the cases occurred in patients the subjects of diabetes; one occurred in a patient at the commencement of the secondary manifestation of syphilis. One case of double facial paralysis occurred in a boy eight years of age after mumps; in another patient, a lad seventeen years of age, an attack of right-sided facial paralysis succeeded to sorethroat with pyrexia. It is also mentioned as an interesting fact that during an epidemic illness (apparently influenza) at Brest, facial paralysis was one of the recognised symptoms.—*Lancet*.

Functional Disorders of Digestion.

J. H. KELLOGG describes certain "new methods of precision" in the investigation of functional disorders of digestion. From observations covering 4,000 cases, he found that the failure to digest starch is one of the most common features in dyspepsia. He commented upon the large amount of sugar found present in the stomach-fluid,

7 or 8 grains per 100 c. cm. of stomach-fluid being frequent. He also noted the interesting relation between starch conversion and proteid digestion. He found 6 cases of complete aepsia in which there was no free hydrochloric acid in the stomach, and the co-efficient of proteid digestion was absolutely nil. He presented the results of a number of tests that he had made as to the influence of various acids on the salivary digestion of starch. He found that it required the following quantities of different acids to neutralise completely the effect of the salivary action: Oxalic acid, 1 part to 10,000; hydrochloric acid, 1 part to 4,000; lemon juice, 1 part to 200, and vinegar 1 part to 200.—*Med News*.

Membranous Enteritis associated with Ascaris Lumbricoides.

DR. IRVING M. SNOW, of Buffalo, N. Y., cites a case in which casts of the intestinal membranes were discharged, during the course of the disease, three inches long, and cylindrical, on the first occasion. After this several smaller portions of membrane were discharged on several occasions. Finally ascarides were discharged. Calomel and santonin then brought away two more. Later others were brought away. The casts ceased to be discharged after the worms were got rid of. The history of this case is peculiar. The casts evacuated were accompanied by blood and mucus, but, contrary to the usual case, there was no pain nor tenesmus, or other uncomfortable symptom. A similar case was read, reported by another observer. In this case, fourteen days after discharge of fibrous membranes, ascarides were passed.—*Journ Amer. Med. Assoc.*

Colitis in Infancy and Childhood.

DR. EDWARD ANDERSON, of Brockville, Md. says:—"The disease prevails in hot weather, due to intestinal fermentation, to which hot weather is conducive. This is made more liable to occur by impaired health, especially so in artificially-fed children, as is well known. Undigested material accumulated in the intestine conduces to the development of the disease, which should be eliminated by cathartics or washed out by injections. Cases illustrating the management employed by the author were read. He insists upon the giving of mercury and enemas. Change of diet should be carefully made. Mercury is the drug advocated. Blue mass should be administered until symptoms abate, together with warm-water injections."—*N. Y. Med Rec.*

Optic Neuritis of Gonorrhoeal Origin.

PROFESSOR PANAS reports a case of the above nature, belonging to the class of peripheral neuritis of toxic origin, the primordial agent being the gonococcus. In order to explain its action the author asks whether it is necessary to admit a metastasis of microbes by way of the vessels to the optic nerve? Or, should we think that the gonococcus acts through the toxin which it elaborates? In the absence of full information, the latter hypothesis seems the more acceptable, for all the examinations for the microbe in the ocular tissues were negative, although it must be remembered that it is difficult to obtain cultures of the gonococcus.—*La Medecine Moderne*.

SURGERY.

Etiology and treatment of suppuration.

REICHEL relates his investigations into the predisposition of tissues to suppurate and the disinfection of wounds. Everything tending to promote the absorption of micro-organisms and their products tends to prevent suppuration, whereas the opposite conditions favour

it. Thus the situation and also the structure of tissues have an important influence. Copious and repeated bleedings did not promote suppuration. A single bleeding before infection seemed to hinder it, probably owing to rapid absorption. Loss of blood with the injection of saline fluid rather favors suppuration. Increasing or diminishing the alkalinity of the blood by means of feeding, respectively hinders or promotes suppuration. All causes which increase cell activity and metabolism assist in preventing suppuration. The author then refers to SCHIMMELBUSCH's experiments, in which, after inoculation with anthrax at the root of the tail, the mouse could not be saved by disinfecting the wound. He obtained better results with the less virulent *staphylococcus*. The author comes to the conclusion that in rabbits very extensive phlegmonous processes can be brought to an end by free incision, extirpation of the pus in infiltrated tissues, and plugging the wound cavity with antiseptic gauze. If severe general infection is present the operation, whether carried out antiseptically or aseptically, is without avail. He concludes that strict asepsis, not antisepsis, should be adopted in the treatment of fresh wounds, and that infected wounds and phlegmons should be laid open under aseptic precautions and subsequently plugged with antiseptic gauze, secondary suture being adopted.—*B. M. J.*

Radical cure of Fistula in Ano.

In doing a radical operation for fistula, the following points, according to DR. J. H. BACON, should be observed:—

(1) Never sever the sphincters at more than one place at the same operation, no matter what the complications may be, otherwise incontinence is sure to follow.

(2) Unless all the channels are followed up and laid open the operation will fail of its purpose.

(3) Fistula resulting from tubercular abscess must not be operated upon if there is sufficient destruction of lung tissue to produce hectic fever, sweats, etc., unless the fistula is causing severe painful spasms of the sphincters, then it should be divided at any stage.

(4) After laying the fistula tract open, the wound must be made to heal from the bottom, and as the cutaneous or mucous side of the wound is better nourished, it will throw out a more healthy granulation, that tends to bridge over and close the slower granular surface at the bottom, thus leaving a fistula remaining.

(5) When the fistulous tract is not too complicated it should be dissected out entire, and the wound brought together, beginning at the bottom with continuous catgut sutures and approximating the surfaces in successive layers until the whole wound is closed.—*North-West Med. Jour.*

Surgical treatment of Exophthalmic Goitre.

DR. TUFFIER gives an interesting account of a case where surgical interference caused complete disappearance of all symptoms of the disease, which had resisted all other kinds of therapeutic treatment. The patient was a young woman, aged twenty-seven, who had suffered with the malady for seven years and its beginning was marked by a cystic enlargement of the right lobe of the thyroid gland, which was soon accompanied by severe exophthalmos and the other usual symptoms. Iodine injections, tapping and electrical treatment were all tried in vain, and the patient became so ill that she could not work, and in addition, shewed signs of distress from the pressure which the enlarged thyroid gland was producing on the trachea. It was then decided to perform partial thyroidectomy, and this was successfully accomplished, with the result that the general symptoms rapidly disappeared, the woman now being in good health and able to work. The exophthalmos also almost entirely disappeared, and no

Dr. R. W. FELTON tells us "that with selected men, one might colonise even West or Central Africa;" but we cannot forbear from stating that this wide-spread and loose generalisation does not accord by any means with our own experience in West Central Africa.

A Rare case of Stupor with Forced Feeding for nine Years.

GADELIUS had an interesting case under his care,—that of a tailor, aged 32 years, an assiduous workman, slow, taciturn, but amenable to reason. Insanity of persecution developed, the prominent symptoms being anxiety and insomnia, with neglect of his person and refusal to take food. When spoken to he invariably answered in an undertone, "Fine weather, to-day," and, later on, "I do not know." Forced feeding was carried on uninterruptedly, from April 21, 1883, to February 12, 1892, the body-weight increasing during this period from 46 to 73 kilogrammes (101 to 160 pounds). From April, 1883, to May, 1886, he remained in a condition of complete stupor and anaesthesia. The author considers the prodromic delirium as a quasi-paranoid psychosis in a degenerate subject, and regards the case as a psychosis of exhaustion, being practically a condition of syncope from beginning to end. On awakening from the stupor the patient had lost most of his former knowledge of things and places, but soon recovered it.—*Hygieia*.

Facial Paralysis.

THE conclusions drawn from the observation of eighty cases of facial paralysis by Dr. RUDOLPH HATSCHKE are: Among the eighty cases were ten in which more than one attack had occurred. Sometimes one side, sometimes both sides were affected, and more than once there were third attacks. There seemed to be no tendency for one sex to suffer more than the other, and there was no preference for one side of the face over the other. As a rule, the later attack was more severe, but not invariably so. Two of the cases occurred in patients the subjects of diabetes; one occurred in a patient at the commencement of the secondary manifestation of syphilis. One case of double facial paralysis occurred in a boy eight years of age after mumps; in another patient, a lad seventeen years of age, an attack of right-sided facial paralysis succeeded to sorethroat with pyrexia. It is also mentioned as an interesting fact that during an epidemic illness (apparently influenza) at Bresl, facial paralysis was one of the recognised symptoms.—*Lancet*.

Functional Disorders of Digestion.

J. H. KELLOGG describes certain "new methods of precision" in the investigation of functional disorders of digestion. From observations covering 4,000 cases, he found that the failure to digest starch is one of the most common features in dyspepsia. He commented upon the large amount of sugar found present in the stomach-fluid,

7 or 8 drachms per 100 c. cm. of stomach-fluid being frequent. He also noted the interesting relation between starch conversion and proteid digestion. He found 6 cases of complete aspepsia in which there was no free hydrochloric acid in the stomach, and the co-efficient of proteid digestion was absolutely nil. He presented the results of a number of tests that he had made as to the influence of various acids on the salivary digestion of starch. He found that it required the following quantities of different acids to neutralise completely the effect of the salivary action: Oxalic acid, 1 part to 10,000; hydrochloric acid, 1 part to 4,000; lemon juice, 1 part to 200, and vinegar 1 part to 200.—*Med. News.*

Membranous Enteritis associated with *Ascaris Lumbricoides*.

DR. I. VING M. SNOW, of Buffalo, N. Y., cites a case in which casts of the intestinal membranes were discharged, during the course of the disease, three inches long, and cylindrical, on the first occasion. After this, several smaller portions of membrane were discharged on several occasions. Finally ascarides were discharged. Calomel and santalin then brought away two more. Later others were brought away. The casts ceased to be discharged after the worms were got rid of. The history of this case is peculiar. The casts evacuated were accompanied by blood and mucus, but, contrary to the usual case, there was no pain nor tenesmus, or other uncomfortable symptom. A similar case was read, reported by another observer. In this case, fourteen days after discharge of fibrous membranes, ascarides were passed.—*Journ. Amer. Med. Assoc.*

Colitis in Infancy and Childhood.

DR. EDWARD ANDERSON, of Brockville, Md. says:—"The disease prevails in hot weather, due to intestinal fermentation, to which hot weather is conducive. This is made more liable to occur by impaired health, especially so in artificially-fed children, as is well known. Undigested material accumulated in the intestine conduces to the development of the disease, which should be eliminated by cathartics or washed out by injections. Cases illustrating the management employed by the author were read. He insists upon the giving of mercury and enemata. Change of diet should be carefully made. Mercury is the drug advocated. Blue mass should be administered until symptoms abate, together with warm-water injections."—*N. Y. Med. Rec.*

Optic Neuritis of Gonorrhoeal Origin.

PROFESSOR PANAS reports a case of the above nature, belonging to the class of peripheral neuritis of toxic origin, the primordial agent being the gonococcus. In order to explain its action the author asks whether it is necessary to admit a metastasis of microbes by way of the vessels to the optic nerve? Or, should we think that the gonococcus acts through the toxin which it elaborates? In the absence of full information, the latter hypothesis seems the more acceptable, for all the examinations for the microbe in the ocular tissues were negative, although it must be remembered that it is difficult to obtain cultures of the gonococcus.—*La Medecine Moderne.*

SURGERY.

Etiology and treatment of suppuration.

REICHEL relates his investigations into the predisposition of tissues to suppurate and the disinfection of wounds. Everything tending to promote the absorption of micro-organisms and their products tends to prevent suppuration, whereas the opposite conditions favour

it. Thus the situation and also the structure of tissues have an important influence. Copious and repeated bleedings did not promote suppuration. A single bleeding before infection seemed to hinder it, probably owing to rapid absorption. Loss of blood with the injection of saline fluid rather favors suppuration. Increasing or diminishing the alkalinity of the blood by means of feeding, respectively hinders or promotes suppuration. All causes which increase cell activity and metabolism assist in preventing suppuration. The author then refers to SCHIMMELBUSCH's experiments, in which, after inoculation with anthrax at the root of the tail, the mouse could not be saved by disinfecting the wound. He obtained better results with the less virulent staphylococcus. The author comes to the conclusion that in rabbits very extensive phlegmonous processes can be brought to an end by free incision, extirpation of the pus in infiltrated tissues, and plugging the wound cavity with antiseptic gauze. If severe general infection is present the operation, whether carried out antiseptically or aseptically, is without avail. He concludes that strict asepsis, not antiseptics, should be adopted in the treatment of fresh wounds, and that infected wounds and phlegmons should be laid open under aseptic precautions and subsequently plugged with antiseptic gauze, secondary suture being adopted.—*B. M. J.*

Radical cure of Fistula in Ano.

IN doing a radical operation for fistula, the following points, according to DR. J. H. BACON, should be observed:—

- (1) Never sever the sphincters at more than one place at the same operation, no matter what the complications may be, otherwise incontinence is sure to follow.
- (2) Unless all the channels are followed up and laid open the operation will fail of its purpose.
- (3) Fistula resulting from tubercular abscess must not be operated upon if there is sufficient destruction of lung tissue to produce hectic fever, sweats, etc., unless the fistula is causing severe painful spasms of the sphincters, then it should be divided at any stage.
- (4) After laying the fistula tract open, the wound must be made to heal from the bottom, and as the cutaneous or mucous side of the wound is better nourished, it will throw out a more healthy granulation, that tends to bridge over and close the slower granular surface at the bottom, thus leaving a fistula remaining.
- (5) When the fistulous tract is not too complicated it should be dissected out entire, and the wound brought together, beginning at the bottom with continuous catgut sutures and approximating the surfaces in successive layers until the whole wound is closed.—*North-West Med. Jour.*

Surgical treatment of Exophthalmic Goitre.

DR. TUFFIER gives an interesting account of a case where surgical interference caused complete disappearance of all symptoms of the disease, which had resisted all other kinds of therapeutic treatment. The patient was a young woman, aged twenty-seven, who had suffered with the malady for seven years and its beginning was marked by a cystic enlargement of the right lobe of the thyroid gland, which was soon accompanied by severe exophthalmos and the other usual symptoms. Iodine injections, tapping and electrical treatment were all tried in vain, and the patient became so ill that she could not work, and in addition, shewed signs of distress from the pressure which the enlarged thyroid gland was producing on the trachea. It was then decided to perform partial thyroidectomy, and this was successfully accomplished, with the result that the general symptoms rapidly disappeared, the woman now being in good health and able to work. The exophthalmos also almost entirely disappeared, and no

Dr. R. W. FAYRER tells us "that with selected men, one might colonise even West or Central Africa;" but we cannot forbear from stating that this wide-spread and loose generalisation does not accord by any means with our own experience in West Central Africa.

Dental caries has been extremely prevalent here of late years, and seems on the increase.

The Chemical Society have awarded the Faraday Medal to Lord RAYLEIGH for his discovery of "Argon."

A new element, called "HELIUM," has aroused some attention in Chemical circles.

We are pleased to relate that Sir JOSEPH FAYRER has recovered from his late severe and protracted illness.

We are delighted to inform our readers that Mr. CHRISTOPHER HEATH has been elected President of the R.C.S., England.

There are now two Royal Commissions in working order: One on the aged poor, and the second on "Vaccination."

HARVEY's masterpiece "*Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*" has been reproduced in facsimile from the Frankfort edition, published in 1628.

Numberless accidents with paraffin lamps continue to be reported in London.

SIR JOSEPH LISTER, F.R.S., has been welcomed at Marlborough House by the PRINCE OF WALES who presented him with "the Albert Medal" from the Society of Arts, in recognition of his services in Antiseptic Medicine.

Current Medical Literature.

MEDICINE.

Obstruction of the Bowel Tested by Electricity.

ALTHAUS reports a case of a man fifty-four years old, who for three months had suffered with obstinate constipation. At the time of coming under observation the bowels had not moved for ten days, and the abdomen was distended and tender. The appetite was lost, and a condition of collapse existed, with sunken face and small feeble pulse. The introduction of the long tube proved unavailing, and electric treatment was resorted to. An insulated sound, with a fine metallic end, was introduced into the rectum, and a moistened conductor applied to the abdominal parietes, chiefly in the region of the sigmoid flexure. Through this circuit a primary faradic current was passed, and its force gradually increased until the patient experienced a decided feeling of vibration in the bowel. In the course of the day a copious intestinal evacuation ensued, with wonderful relief to all the symptoms. During the next two days the bowels acted ten times, and in the course of a week the patient appeared quite well.

A second case, in a woman fifty-seven years old, is cited, in which a like result was obtained from similar treatment.—*Brit. Med. Journ.*

Bright's Disease without Albuminuria.

HASTON, after referring to the recorded cases, relates three cases of unquestionable nephritis occurring in patients aged fifty-eight, nineteen, and fifty-nine years respectively. In the first case there never was albuminuria, while the

patient was under observation. In the second case a chlorotic girl was admitted with many of the symptoms of Bright's disease, and yet there was no albuminuria. Two years later she was readmitted, when albumin was present in the urine. In the third case the patient had been under treatment with Bright's disease and albuminuria. Later she was admitted with influenza. The albumin entirely disappeared, but the symptoms of Bright's disease persisted. The author draws attention to the fact that the quantity of albumin present may be of little prognostic importance, and he relates an illustrative case. Albuminuria is a feature of secondary importance in Bright's disease; it may occur in health, it may exist in large quantities in cases of Bright's disease with few symptoms, and it may be absent in uremia. As DIEULAFOY says, the important thing in renal disease is not so much what passes out in the urine, as what remains behind in the body.—*Arch. Gén. de Méd.*

A Rare case of Stupor with Forced Feeding for nine Years.

GADELIUS had an interesting case under his care,—that of a tailor, aged 32 years, an assiduous workman, slow, taciturn, but amenable to reason. Insanity of persecution developed, the prominent symptoms being anxiety and insomnia, with neglect of his person and refusal to take food. When spoken to he invariably answered in an undertone, "Fine weather, to-day," and, later on, "I do not know." Forced feeding was carried on uninterruptedly, from April 21, 1883, to February 12, 1892, the body-weight increasing during this period from 46 to 73 kilogrammes (101 to 160 pounds). From April, 1883, to May, 1886, he remained in a condition of complete stupor and anaesthesia. The author considers the prodromic delirium as a quasi-paranoid psychosis in a degenerate subject, and regards the case as a psychosis of exhaustion, being practically a condition of syncope from beginning to end. On awakening from the stupor the patient had lost most of his former knowledge of things and places, but soon recovered it.—*Hygiea.*

It was then decided to perform partial thyroidectomy, and this was successfully accomplished, with the result that the general symptoms rapidly disappeared, the woman now being in good health and able to work. The exophthalmos also almost entirely disappeared, and no

After unpleasant symptoms have followed. Dr. TUPPER believes the success of the operation to lie in partial removal of the gland, which he thinks gives better results, both immediate and future, than complete extirpation of the organ.—*Lancet*.

The treatment of Hydrocele.

The treatment of hydrocele by the injection of irritating substances is sometimes very painful. The use of cocaine as a local anesthetic in the ordinary way not being free from danger, NICOLAI has since 1889 employed the following method:—The usual antiseptic precautions being taken, the hydrocele is punctured with an ordinary trocar; about one-third of the fluid is allowed to flow away, then 3 to 4 c. cm. of a 1 per cent. watery solution of cocaine is injected into the bulk of the serous effusion remaining in the sac, through the canula of the trocar with a syringe of the capacity of 4 c. cm. The scrotum is then gently manipulated, and after waiting four or five minutes the remainder of the serous fluid is drawn off. Next tincture of iodine, either pure, or mixed with one-third of water, according to the age of the hydrocele and that of the patient, is injected. The scrotum is again gently manipulated, and after four or five minutes the iodine is allowed to escape. The operation done in this manner is painless. The method has the advantage of utilizing a natural aseptic fluid as the excipient of the injection. Moreover, the quantity of cocaine absorbed by the serous surface is less in the case of a serous solution than of a watery solution of the medicament of the same strength.—*Brit. Med. Journ.*

The cure of Lachrymal Obstruction.

IN cases of lachrymal obstruction, it is not always easy to ensure its permanent patency after operation. The *New York Medical Record* describes a method, devised by DR. WALTER VILAS, of Texas, which, it is said, has been tried in a number of cases of lachrymal obstruction and abscess with unfailing success. The *modus operandi* is this: After the preliminary slitting of the canaliculus, a small-sized probe, armed with a canula, is passed and withdrawn, leaving the canula *in situ*, through which is pushed a small piece of silkworm gut, its lower end being brought out through the nose. Having withdrawn the canula, a split aluminium shot is fastened to the lower end of the gut, and the latter is pulled up until its further progress is obstructed, when another shot is fastened to the gut at its exit from the upper opening and the superfluous gut cut away. The shots and gut are left in place until the case is cured.—*Medical Times*.

Laparotomy and penetrating wounds of the Abdomen.

FILIPPO reports a series of 13 cases of abdominal injury with penetration in which laparotomy was performed. In six cases in which the operation was merely exploratory, speedy cure resulted; in five, one or more wounds of the intestines or stomach were found, and of these 1 died, owing to the fact that one wound was overlooked at the time of operation. In two cases the left lobe of the liver was injured, and there was copious hemorrhage; of these, 1 is alive, the other died 38 days after operation from pneumonia. The author concludes that laparotomy, as a rule, gives good results in these cases, if done early. During the operation all the abdominal viscera should be most carefully examined, lest any small wound be passed by. Lavage of the abdominal cavity with some antiseptic is useful. Subsequent ventral hernia is not to be dreaded, whether incision is made *en site* or in the linea alba. Suppuration of the abdominal walls is a not an infrequent sequel after laparotomy for penetrating wounds.—*Brit. Med. Journ.*

OBSTETRICS AND GYNECOLOGY. The use of the Sponge Pessary During Menstruation.

DR. ALEXANDER DUKES says:—"Having for some time past recommended married patients to introduce a clean, soft sponge, squeezed out of warm solution of Condy's fluid into the vagina during the catamenial flow, and thus dispense with the use of diaper or sanitary towel. I find the consensus of opinion decidedly in favor of the proceeding. The sponge should be cone-shaped, longer than broad, and a stout cord passed through (forming a loop when ends are knotted), through which a finger can be passed when it becomes necessary to withdraw the tampon.

During normal menstruation nature is endeavouring to throw off a certain quantity of redundant blood, &c. Why this should be retarded in its exit, and collected in either a diaper or sanitary towel, and kept in close contact with the external parts to the wearers' annoyance and discomfort, I fail to see, when by the simple plan described, all this can be avoided, natural flow accelerated, and the external parts kept from contact with the discharge. The sponge needs only to be hidden in the vaginal passage (thus giving room above it for some of the menses to collect) and by its own absorption and swelling, seal the canal and thus prevent any external flow. I direct the pessary to be removed every six hours, and the vagina then thoroughly syringed out with hot water. The sponge to be thoroughly cleansed by the wearer in weak saline solution squeezed out of Condy's fluid and re-introduced.

By this means I am assured the "period" is shortened by two or three days in many cases, and the comfort experienced, more especially by ladies travelling, (having no soiled diapers to carry with them or 'sanitary towels,' for which an opportunity to destroy does not always offer)! This must be my excuse for calling attention to, and recommending the proceeding to the consideration of the profession."—*Med. Press and Circ.*

Removal of the Uterine Appendages for Nervous Diseases.

Most gynecologists are at the present time averse to removing the ovaries and tubes for nervous diseases; but DR. W. H. BAKER thinks that disease of the uterine annexa is sometimes an unrecognised cause of neuroses. He is of opinion that the adhesions resulting from attacks of localised pelvic peritonitis is a not infrequent source of nervous disease, either from the presence of the pseudo-membranes in themselves, or from the interference which they offer to the functional activity of the organs involved. The extent and form of the pelvic disease is no indication of the character or degree of the resulting nervous manifestation. A most thorough pelvic examination should be made under anesthesia in every obscure case of nervous disease in a woman, occurring during the age of menstrual activity. Finally, DR. BAKER thinks that some forms of uterine disease may occasion an amount of nervous disturbance which may require the removal of the healthy Fallopian tubes and ovaries, as the simplest and safest means of cure.—*Boston Med. and Surg. Jour.*

When shall Celiotomy be performed in the Treatment of Puerperal Sepsis?

DR. EDWARD P. DAVIS discusses this important practical question, and comes to the following conclusion:—"When the uterus and vagina have been thoroughly disinfected by the curette and douche, and the lymphatics of the pelvis and peritoneum have been well drained by saline purgatives, if the patient does not improve, the question of Celiotomy must be considered. If an infective focus can be distinctly outlined under anesthesia, it must be, if possible, extirpated. Vaginal

Celiotomy will often drain a pelvic abscess with the least disturbance, and give valuable time for an improvement in general condition. If vaginal hysterectomy, with removal of the tubes and ovaries can be performed, it may supplement the vaginal drainage of an abscess. If it cannot be performed, Suprapubic Celiotomy, with amputation or extirpation of the uterus and appendages, and vaginal drainage, is indicated. Celiotomy, flushing with saline solution, and drainage are also indicated in commencing infection of the general peritoneal cavity.—*American Journal of Obstetrics*.

Later evils following Retention of Placental Relics.

HARTMANN and TOUPET have prepared a valuable monograph on the changes which nonseptic fragments of placenta may undergo when left attached to the uterine wall. These changes are (1) simple sclerosis of the placental tissue, (2) benign deciduoma, (3) hydatidiform mole, and (4) malignant deciduoma. In all, chorionic villi are to be detected by aid of the microscope. By benign or innocent deciduoma is understood the true "placental polypus" and more sessile growths, in which there is distinct evolution going on in the chorionic villi, and no sclerosis of the connective tissue. The growth does not, however, recur after thorough removal. The authors relate a case where, as usual, the prominent symptom was frequent metrorrhagia. IEGARS and LEVI (*ibid.*) describe a very distinct case of placental polypus, with the same symptoms. The malignant deciduoma which HARTMANN and TOUPET term "chorioncell sarcoma," and the hydatidiform mole, are, in their opinion, related. In the latter, so long and so well known to the obstetrician, just as in the former, which appears to be a disease but recently recognised, the growth tends to invade and even perforate the uterine wall. In these graver, as in the less serious changes in retained placental tissue, uterine hæmorrhages are always an early and prominent symptom.—*B. M. J.*

Analysis of 6,777 Cases of Midwifery.

DR. J. F. W. ROSS gives an analysis of 6,777 cases of midwifery which his father had conducted. He referred to many interesting features connected with the cases. Although a busy practitioner, the late Dr. Ross kept a full account of all the important items connected with each case. The mortality of mothers was 89, the largest losses being from two epidemics of puerperal fever. The reader traced the disease in its course through each epidemic, and showed how careful his father was in regard to cleanliness and change of apparel in those pre-antiseptic days. He had made two runs of 650 cases without a death. There were 16 deaths from placenta prævia. There were 19 cases of version. There were 5,409 head presentations, 148 breech, 58 foot, 5 breech and foot, 25 face, 7 brow, and 34 arm and shoulder. Forceps were used 491 times. Latterly he had used them oftener, with a lessened mortality rate and a less number of lacerations of the perineum. He believed the forceps properly used were conservative to the perineal body. Chloroform was used in 455 cases. There were 48 cases of retained placenta, and 27 perineæ were torn.—*Canadian Prac.*

Indications for Induction of Abortion.

DR. JEFFE, from a study of the literature of the last ten years, fixes the indications for inducing abortion as follows:—

Absolute indications: 1. Uncontrollable vomiting of pregnancy. 2. Encarceration of the gravid uterus. 3. Obstruction of the pelvic outlet by tumors or exudates. 4. Progressive and pernicious anemia. 5. Grave chorea.

Relative indications: 1. Great contraction of the pelvis with the conjugata vera below 5 cm. 2. Pulmonary emphysema with signs of degeneration of the heart. 3. Nephritis. 4. Chronic heart disease. 5. Other general diseases of the

mother which would jeopardize her life at the time of delivery.

He holds that a conjugata vera of 6 cms. and advanced pulmonary tuberculosis should not be regarded as indications for abortion. He does not think it just to sacrifice a future life for one that is "certainly lost."—*Med. and Surg. Rep.*

Occipito-Posterior Positions.

DR. VAN PRYMA concludes an article on this subject as follows:—In conclusion, I wish to emphasize the vital importance of recognizing the position in vertex presentations; to insist that, as a rule, cases of occipito-posterior position should be left for the natural forces to effect delivery—forces which, in the vast majority of cases, are not only entirely adequate, but in these cases will accomplish the object better than the most skilled instrumental or manual interference.

"Further, I desire to maintain that flexion is essential to natural rotation; that rotation is frequently delayed until the head is very low; that the character of the pains is a very important factor; that the complete anesthesia, the mobility of the head, even when deep in the excavation, is often quite surprising that in occipito-posterior position the blades of the forceps must be applied well forward to insure a firm hold; and that, after the head reaches the perineum, extreme flexion must be maintained until the occiput has passed over the perineum; and, lastly, that no hard-and-fast rules can be formulated to cover all cases, but that much must necessarily be left to the judgment of the operator, based on a consideration of all the conditions involved."—*Buffalo Med. and Surg. Journ.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Normal Absorption of Fat and the Relation of the Pancreas to Absorption of Fat.

DR. VAUGHAN HARLEY, in experiments made to determine the relation of the pancreas to the absorption of fat in dogs, which are recorded in the current number of the *Journal of Physiology*, pursued the following plan:—The animals were kept fasting for two days and the bowels were daily washed out with an enema of hot water, a small glycerine enema being subsequently given to effect the expulsion of the water. On the third day the pancreas was removed under an anæsthetic, the enemata being continued for two days. These animals were compared with other that were intact. Each set of animals were then supplied with a measured quantity of warm milk, and after a certain number of hours, varying in different cases, the animals were killed and the entire contents of the stomach and intestines separately analysed. In the intact animals the maximum rate of absorption of fat occurs about seven hours after the ingestion of food, for normally a dog absorbs from 9 to 21 per cent. of the total fat given in from three to four hours, from 21 to 46 per cent. in seven hours, and 86 per cent. in eighteen hours. In a normal dog the passage of fat from the stomach varies with the individual as well as with the time allowed for digestion, but in eighteen hours the whole has entered the intestines. In dogs which have had the pancreas removed the quantity of fat given is not only again recovered, but a surplus is found which is probably derived from the intestinal secretion or excretion. Dr. VAUGHAN HARLEY also found that the capability of passage of fat from the stomach is very much delayed by the extirpation of the pancreas, such dogs only passing in seven hours from 9 to 22 per cent. through the pylorus instead of, as in normal dogs, about 86 per cent.—*Lancet*.

Preservation of Urine for Examination.

In order to arrive at the true condition of a sample of urine, the earlier it is examined the better. It is, however, sometimes impossible to obtain it for examination for many hours, or even days, after it has been passed, and it is then often entirely changed. Various substances have been recommended as anti-ferments and preservatives, but all have objectionable features. Accident recently led us to try *Thymol*, and the results were as gratifying as they were unexpected. Though the substance is well-nigh insoluble in water, and a crystal added to urine remains unattacked, so far as appearances go, for days, a very minute quantity of it sufficed to preserve a couple of ounces of urine apparently unchanged for several days.—*Med. News*.

Method of Making a Permanent Dry Brain Preparation.

DR. ALFRED W. CAMPBELL gives the following method:—

1. As soon as possible after removal from the cranial cavity, the brain is stripped of its membranes and placed in a saturated solution of perchloride of mercury (seven and a half per cent.), care being taken to avoid distortion of its configuration. In this solution it is allowed to remain for forty-eight hours, at the end of which time its shape will be fixed.
2. Wash in water and then harden in methylated spirit for from three to five weeks. (It is better that the spirit be changed two or three times during this period.)
3. When quite firm, immerse in oil of turpentine and place for three days in an incubator heated up to 45°C.
4. Change into melted Cambridge soft paraffin, and allow to remain in the incubator just above the melting point of the paraffin for from four to five days.
5. Extract, cool in water, clean away all the paraffin from the surface and sulci of the preparation, and finally apply a thick coat of spirit varnish.
6. The brain can then be freely handled, and may further be painted with the usual mixture of oils, colors, turpentine, and gold size.—*Liverpool Med.-Chirur. Journ.*

A new Procedure for Studying Tubercle-Bacilli in Sputum.

SPENGLER recommends the following procedure for the detection of tuberclebacilli in sputum: To the sputum in a beaker are added an equal quantity of luke-warm water alkalised with sodium hydroxide and from 1.5 to 15 grains of powdered pancreatin. The mixture is well shaken, and from 1.5 to 15 grains of crystallized carbolic acid added, and the whole is placed for three hours in the thermostat. When a sediment has formed, the supernatant fluid is decanted and the examination is made. If the sediment is excessive, water is added, alkaline, if necessary, and the mixture stirred and digestion permitted to proceed. In the course of a few hours a small sediment will have formed, which is again washed and then centrifugated or dried upon filtered paper. In the case of pure cultures of tubercle-bacilli it has been found that protracted digestion results in no harm, but in the case of sputum it is desirable that this be not too long continued.—*Canad. Prac.*

Pneumococci in Hydatid Cyst.

GALLAIRD relates a case under his care in which a large suppurating cyst of the liver was opened and drained. The pus, examined microscopically, was found to contain hooklets and pneumococci, without any other microbes. The patient was not then suffering, nor had he ever suffered from pneumonia.—*Brit. Med. Jour.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.**Small-Pox and Vaccination in Russia.**

RELIABLE statistics relating to vaccination and small-pox are not often forthcoming in this country. This renders the following figures even more valuable than they would otherwise be. The figures were collected by Dr. A. N. SOTIN and published by him in a dissertation to the St. Petersburg Academy last year. He was led to collect the statistics in the following manner: The *colod*, or subdistrict, of which he was in charge, lay in the western corner of the Mologa *uyezd* or district, in the government of Yaroslavl. Observing that an epidemic of small-pox was approaching from the east, DR. SOTIN personally examined every child under fourteen years of age in his district before the disease arrived. The total number of children examined was 1564, distributed amongst 665 families, and in thirty villages. He found that 1035 had been vaccinated and had visible scars; 75 children formed a second group of doubtful cases, which were said to have been vaccinated, but in which no scars were visible; and 434 had never been vaccinated. The small-pox arrived and a widespread, though not very fatal, epidemic resulted. It was then found that of the 1035 "vaccinated" children only 16 or 1.3 per cent. had contracted the disease; of the 75 "doubtful," 35, or 46.6 per cent. suffered; while of the 434 "unvaccinated" children as many as 244, or 56.6 per cent. caught the disease. In other words, the unvaccinated suffered to an extent forty-five times as great as the vaccinated. Further, it was observed that in 189 families all the children were unvaccinated, and in these families if one child sickened with the small-pox the disease spread (with only seventeen exceptions) to every other child in the house. On the other hand, in houses where some children were vaccinated and others not, the disease always attacked the last, and the first escaped. DR. SOTIN believes that there is no danger from vaccination performed during a small-pox epidemic, but that general vaccination will with certainty cut short an epidemic, and that the immunity following vaccination does not last more than eight years, at the end of which time revaccination is necessary.—*Lancet*.

Period of Infection.

THE Pennsylvania State Board of Health has adopted the following regulations in the diseases mentioned below:—

Small-pox.—Six weeks from the commencement of the disease if every scab has fallen off.

Chicken-pox.—Three weeks from the commencement of the disease, if every scab has fallen off.

Scarlet-fever.—Six weeks from the commencement of the disease, if the peeling has ceased, and there is no sore nose.

Diphtheria.—Six weeks from the commencement of the disease, if sore throat and other signs of the disease have disappeared.

Measles.—Three weeks from the commencement of the disease, if all swelling has subsided.

Typhus.—Four weeks from the commencement of the disease, if strength is re-established.

Typhoid.—Six weeks from the commencement of the disease, if strength is re-established.

Whooping Cough.—Six weeks from the commencement of the disease, if all cough has ceased.

Under judicious treatment the periods of infectiousness may be considerably shortened.

Length of Quarantine.—Teachers, or children who have been exposed to infection from any of the following diseases, may safely be readmitted to the school, if they remain in good health (and have taken proper means for disinfection), after the following periods of quarantine :—

Diphtheria, twelve days ; scarlet fever, fourteen days ; small-pox, eighteen days ; measles, eighteen days ; chicken-pox, eighteen days ; mumps, twenty-four days ; whooping-cough, twenty-one days. Adults may be readmitted immediately, if they disinfect their clothes and persons.—*N. Y. Med. Rec.*

Variety in Diet.

A NUMBER of facts conspire to throw a somewhat new light on questions of dietetics, or at least to show that these problems are more complex than they have been by some supposed. It has been usual to speak of a "mixed diet," meaning thereby one composed in part of animal and in part of vegetable food, one containing proteids, fats, and carbohydrates, approximately in such proportion as they are required by the organism ; but when we see the effect upon disease produced by very small quantities of certain selected portions of animals commonly used as food, such as thyroid gland, suprarenal gland, and bone marrow, the suspicion arises that these are but the more pronounced expressions of a widespread principle, and that such marked differences in therapeutic effect between certain organs may be associated with similar differences in nutritional value between the various portions and kinds of meat which we consume. We may surmise too that the modes of preparation may have a considerable influence, and that while good cooking may be, as it should be, a preparation for and an aid to digestion, certain processes in cooking may do much more harm to the nutritional value of our food than is explained by the mere change in its physical properties, the hardness, toughness, etc., which they produce. The destruction of the antiscorbutic properties of milk by condensing, overcooking, and sterilisation, is a case in point, and we commend to the British farmer the interesting question whether and how far the prolonged freezing of meat may interfere with its finer nutritional value. Healthy men, who have a great reserve of digestive power, can derive nutriment from almost any food, but for people of feebler frame a mixed diet must mean one in which variety of substances exists of whose nature and of whose differences *inter se* we as yet know nothing. The healthy man, by taking plenty, finds among it what he wants, but until we know much more than we do of the varied value of different foods and different modes of cooking, we must at least afford variety to our invalids, and protect them from a monotony in diet which may perchance be debarring them from the one thing needful for their nutrition.—*Brit. Med. Journ.*

Food for Infants.

WHEN predigestion of food is to be combined with sterilising, as is very often necessary in cases of illness, employ the following formula for a sterilized peptonized milk mixture : R Water, 8 ounces (250 grammes) ; one-half of a peptonizing tube or one peptonizing tablet. Dissolve. Add milk, 8 ounces (250 grammes). Peptonize. Then use : Peptonized milk, 2 ounces, (62 grammes) ; cream, 1½ to 2 ounces (45.5 to 62 grammes) ; milk-sugar, 1 measure ; water, enough to make 8 ounces (250 grammes). Sterilize by placing over brisk, but not too hot fire for forty-five minutes, removing hood of sterilizer and leaving lid slightly ajar. Temperature of milk does not go above 90°C. (194°F.), its digestibility thus not being affected. Safe for use for twenty-four hours.—*J. F. CHURCH GRIFFITH, Univ. Med. Nagar.*

"Kissing the Book."

THE Legislature of Pennsylvania has decreed that the oath on the Bible shall be dispensed with. The Governor of the State has indicated that he will approve of the amendments to that end. While it has always been at the option of the swearing citizen to "affirm" or to take the oath, the average person has not known of this alternative, and has done as directed when told to "kiss the book." This latter has the tradition and awe of the ages of court procedures behind it, but the multitude cannot fail to recognize the change as a modern reform. The silent work of the theory of the germ production of disease has undermined the time-honored process that has been winked at and tacitly continued by the police and other magistrates. These latter are not all of them "posted" on the properties of a kiss-moistened leather-covered book to hold and to propagate the bacilli of disease, and the presumption is that not a few of the Pennsylvania Dogberries will regard the amending act as a blow against the defenses of justice. To such no doubt the removal from their desks of the dirty greasy Bible will appear as a misfortune and an ill-advised innovation. To our bacteriologists and sanitarians, however, it will stand as a mile-post on the road of progress.—*Journ. of the A. M. A.*

Is a Private Hospital a "Nuisance" ?

THE Vice-Chancellor of Ireland has just given judgment in a case which will have interest for many outside Dublin. A lady leased a house in Fitzwilliam Square, and devoted it to the purposes of a private hospital for non-infectious cases. Lord Pembroke, as the owner, applied for an injunction on the ground that her act was a breach of the clause in the lease, which provided that no "offensive or noisy trade, business, or profession whatever," should be carried on in the premises, and the question was whether a hospital came within the meaning of the term "offensive." It was further contended that the adjoining property would be depreciated in value. The Vice-Chancellor held that the case had been proved, that there was a breach of the covenant in the lease, and he accordingly granted an injunction. Against this decision an appeal is to be taken.—*B. M. J.*

—:—

THERAPEUTICS AND PHARMACOLOGY.

Sodium Bicarbonate in Diseases of the Stomach.

M. DUJARDIN-BEAUMETZ publishes a paper on this subject, in which he gives the results of his labors as well as those of a number of other experimenters. The following are the principal conclusions :—

- (1) Sodium bicarbonate excites gastric secretion.
- (2) When the dose is small, the increased acidity is slight and variable.
- (3) When it is a medium dose, the increase of hydrochloric acid is considerable.
- (4) When the dose is large, the period of excitation is prematurely arrested.
- (5) The excess of hydrochloric acid varies according to the doses, reaching its maximum with small doses in two hours, with medium doses in three hours, and with large doses in four hours.
- (6) The bicarbonate should always be given an hour before eating.
- (7) At the beginning of a meal the administration of the bicarbonate appears to suspend the secretion of pepsin. After the meal the exciting action becomes attenuated.

(8) In chemical dyspepsia, in cases of hypochlorhydria, the dose must be given an hour or half an hour before eating and in hyperchlorhydria during the meal or from three to four hours afterwards.

(9) In muscular dyspepsia, when there is a tendency to stasis or to dilatation of the stomach, the dose should be given during the meal or an hour afterwards.

(10) That the best alkaline waters to be employed in the treatment of diseases of the stomach are those containing sodium bicarbonate.—*Gaillard's Med. Journ.*

Action of Iodine on the Temperature of Phthisical Patients.

FROM clinical observations CERVELLO concludes that iodine introduced either by the cutaneous or subcutaneous route, is capable of lowering the febrile temperature to normal. He made use of DURANTE'S solution: pure iodine, 1 gram; iodide of potash, 10 grams; distilled water, 100 grams. One cubic centimeter of this is injected daily. CERVELLO attributes the action of the iodine to a double mechanism—as an antiferment and as a destroyer of the pathogenic agents by accelerating metamorphosis of their products. It is possible that this agent may prove a curative measure in tuberculosis.—*N. Y. Med. Rec.*

The Therapeutic action of Chloroform in Parturition.

IN all literature, DR. J. E. D. JONES says, there are reported not more than forty cases of death from chloroform during labor. He has used the anæsthetic, given every half hour for from twenty to forty hours, without any trouble following. He has seen a profound chloroform operation in obstetrics, lasting for three or four hours without grave effects. He objects, however, to the careless use of the anæsthetic. The alteration in the vasomotor system of a pregnant woman enables her to resist the toxic action of chloroform to this wonderful extent. Is the use of chloroform in labor for the relief of pain alone justifiable? He believes it is not only justifiable, but that it would be inhuman to withhold it. He believes that it is the anæsthetic of all others peculiarly adapted to parturition. At what stages of parturition is chloroform applicable? For pain in any stage in small quantities. To remove muscular rigidity of the cervix or perineum a larger quantity is required, until there follows complete muscular relaxation. Does chloroform tend to prevent uterine contractions? If given in sufficient quantity, it will do this. Does its use tend to promote hæmorrhage? He has never seen a greater tendency to hæmorrhage after than without its use. In 2,000 cases of labor which he has attended he has given chloroform in 1,500 without ill effects following.

AN OUTBREAK OF CHOLERA IN THE DINAJPUR JAIL.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Would you please give a little space in the *Record* to the publication of the following note of an outbreak of cholera in the Dinajpur Jail:—

On the 5th May last, an undertrial prisoner was brought from a cholera-infected part of the district to the jail. On the 7th, two days after his admission, he was attacked with cholera. On his first complaining sick, there was no reason to suspect cholera, so he was sent to the hospital for treatment. He was not long there, however, before the symptoms developed and the disease ran a rapid course, terminating fatally in 10 hours. On the first suspicion of its being cholera, the ward was emptied of all its other occupants and every precaution taken to prevent the spread of the disease. No other cases occurred till the 13th, when two others were attacked at night and six more the next day, the 14th. On this day I ordered every prisoner in jail 10 minims of sulph. acid dil. and two grains of quinine morning and evening. This was continued for a considerable time. On the 15th two more cases occurred, after which the epidemic may be said to have ceased, as there was only one case on the 18th (an attendant on the cholera sick), one on the 23rd, (a weakly patient in the hospital) and one on the 25th, (a sweeper who had worked in the cholera ward all through.)

A sudden outbreak of 11 cases in three days seemed to threaten a serious epidemic, especially within the walls of a jail. This jail is a small enclosure and had a population of 180 souls within its walls, besides jail officers. There were no means at hand to at once remove a portion even of the prisoners from within, and it was impossible to prevent all contact between the attendants on the cholera sick with the other prisoners and jail officers, and yet the epidemic was cut short when it threatened its worst. Every endeavour was made by segregation, disinfection, &c., to prevent the spread of the disease, both after the occurrence of the first case on the 7th and subsequently, but to me these measures do not seem sufficient to account for the sudden cessation of this outbreak, among a lot of men so closely connected. Can it then be attributed to the protection afforded by the administration of the sulphuric acid and quinine? I am inclined to believe it can, and that it deserves a further trial. It has been proved that the cholera microbe ceases to exist in the presence of both these drugs, and if these drugs are present in the alimentary canal, the microbes can have no effect in producing the disease, but must themselves die. With reference to my inability to remove any of the prisoners from the jail enclosure, I must explain that provision is made at the Jail Depot at Calcutta for such contingencies, where on application a supply tent, equipage, &c., can be obtained. I wired for tents on the 14th, but they did not arrive till the 18th.

Yours &c., B. M. BLAKER,
Civil Surgeon, Dinajpur.

THE LATE DR. J. M. COATES.

To the Editor, "INDIAN MEDICAL RECORD."

SIR,—Every one who knew the late DR. COATES will appreciate the kindly terms in which the press has spoken of him. Apart from his high reputation as a medical gentleman, he was known to be a man of a most generous disposition and a very sympathising spirit. Wherever he went, he made friends, and he was liked as well by Europeans as by natives. There was always something so winning in him that one was irresistibly led to have the highest regard and esteem for him. Full of humour, the facetious remarks he was so fond of making by the bedside of his patients must have considerably helped in buoying them up with hope and dispelling their ills like a charm. Himself the father of a large family, he was very fond of children; and when he visited his patients, European or native, he always indulged himself in the pleasure of taking little children in his arms, and caressing them. He was held in such universal regard and esteem that, if a movement were set on foot to perpetuate his memory, subscriptions would, I am assured, come pouring in. Many European and Native gentlemen have already spoken to me on the subject, and told me that they would be glad to subscribe to any movement intended to perpetuate the memory of the man who has so suddenly passed away. I have no doubt that, if the Editors of the three medical journals that are published in Calcutta—DR. SIMPSON, DR. WALLACE, and DR. FERNANDEZ,—were to organize a movement with the co-operation of representative gentlemen of different nationalities, the success of such a movement would be assured, as there are many gentlemen who are ready to subscribe.

For my part I had the highest admiration and the greatest regard for DR. COATES, both in his professional and private capacity. His attendance on his patients was never of such brief duration as is proverbially known as "a doctor's visit." Possessing, as he did, a heart overflowing with kindness and sympathy, often and often did he refuse to take fees from patients who could ill afford to pay him. Always alive to the interests of his patients, he used often, on the same day, to pay them a second and a third visit of his own accord; and when he was offered a fee, he used to remark, with an expression beaming with sympathy: "Did you send for me? Please keep that money in your pocket, my friend. It will be of greater use to you."

Just one day before his death I had the honor and the pleasure of receiving a visit from him. It was one of those friendly visits which he used to pay my family whenever he returned to Calcutta. He seemed, as usual, to be full of humour and in excellent spirits; and he gave me a long account of his travels with his wife on the Continent. He was in robust health; and in taking leave of me, he jumped, to my surprise, a flight of two or three steps at the landing, and I remarked to him, "Doctor, you seem to have all the vigour and buoyancy of youth." He laughed heartily, and got into his conveyance. Imagine my surprise and grief to hear the next day of his sudden death.

Humorous as he always was, he was not insensible of a future existence. On a mournful occasion twelve years ago he sent me a letter of condolence which was a source of comfort and solace to me, and I have no doubt it will prove the same to the loved ones he has left behind, I take a few extracts from the letter, which is dated from the—

Medical College, "2nd April 1883."

"Dear Mr. Cranenburgh,—I know not how to show you my sympathy. Such losses and sufferings have to be felt to be known, and an outsider cannot enter within such a circle. Of two things I feel as sure as can be: (1) That however much one longs and tries for intercourse with the spirit that's gone, and however great our efforts to peer into the great eternity which is so near us, we cannot do it. It would not be good for us if it were permitted, for we would spend our time, and lose ourselves—perhaps make idols of such an intercourse. (2) We know that the same God Who gave Himself for us has us in His keeping as much before as after our demise, and we may fully and freely trust to His keeping the dearest object we possess, and even our own destiny. I greatly sympathize with your young family. Their loss is greatest—that of a mother's love and such an amiable and loving mother too.

Yours sincerely, J. M. COATES.

Verily, a great and a good man has passed away. The medical profession should be proud that they had such a man as one of their number, and I feel sure, that if the subscriptions were restricted to the medical profession alone, more than enough would be collected to perpetuate the memory of the late DR. COATES.

Yours, &c., D. E. CRANENBURGH, *Pleader.*

CALCUTTA, 15th July 1895.

DR. McCABE DALLAS ON HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Kindly permit me to communicate to DR. DALLAS of Kumbhir, through your journal, an answer to his question, what are the qualifications of Civil Hospital Assistants, published in your issue of the 16th March last.

DR. DALLAS is a medical officer of a tea garden in Cachar District, where young men of good qualifications do not like to go for an employment. Besides, the Bengalees entertain a very bad idea in respect to tea garden masters, and this has been very recently proved in a simple case played out by DR. DALLAS himself. In the issue of the 16th April 1895, DR. DALLAS asked for a good doctor babu, a man with experience, and having a knowledge of English as far as to be able to read and understand an English prescription. He wanted to pay Rs. 40 for the first six months and afterwards Rs. 50 per month.

I read his letter of the 16th March issue, and could understand thereby that during his "experience" he did not get a good doctor babu for his service. I accordingly advised a friend of mine, whose English qualification was up to the F. A. standard of the Calcutta University, and who cut a good figure in the final examination of the Campbell Medical School, Sealdah, and induced him to go there in the

hope that with his services DR. DALLAS might be well satisfied, and so wipe away the idea he has been entertaining so long about the qualifications of the Civil Hospital Assistant class. But to my great regret DR. DALLAS could not first understand whether the candidate was able to read and understand an English prescription, though his English qualifications were clearly stated in his application for the post. However, the applicant wrote him again in detail, and was waiting for a letter of appointment, when a telegram arrived, asking him to accept the post on Rs. 30 (!) while the advertisement was for Rs. 40, rising to Rs. 50.

Mr. Editor, do you think that such a man like DR. DALLAS could ever expect to get a good doctor babu for his services under such circumstances?

Now Sir, my answer is that so long as DR. DALLAS is not willing to offer a good pay for a good doctor babu he is not likely to know what the qualifications of Civil Hospital Assistants are.

Yours &c., RATIKANTA MOZUMDAR, C.M.S.,
Medical Practitioner.

CHAUSHONDI DISPENSARY, JAGATI P. O., 3th July 1895.

T. CUNNOOSWAMY PILLAI MEMORIAL FUND.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—At a preliminary meeting of the Hospital Assistant students, held on the 11th May 1895, to express their regret and sympathy in consequence of the great loss sustained in the sudden death of Mr. T. Cunnooswamy Pillai on the 4th May 1895, of apoplexy, a committee was formed with power to take necessary steps towards perpetuating the memory of the deceased.

The late MR. CUNNOOSWAMY PILLAI, a first-class Hospital Assistant was appointed Lecturer on Materia Medica to the Hospital Assistant Department, and also assistant Professor of Midwifery, Ophthalmology, and Dental Surgery of this College in the year 1866. Since then he used to send out from the College every year a batch of not less than 80 Hospital Assistants, well trained in matters social and professional—a fact which is well known among his scholars and friends.

The object of the Committee so formed is to raise a fund amongst his scholars, friends and sympathisers, so as to yield an annual income that may be sufficient to found a gold medal in his name for the Hospital Assistant students in the subject of which he was the lecturer.

A sum of over Rs. 250 is already promised by the Hospital Assistant students alone, and a large sum is expected from the professors, assistant professors, students of the College department of Madras and also from his friends, old students, and sympathisers of this Presidency.

A general meeting with one of the professors in the chair is being arranged to be held very shortly in the College, when a General Treasurer for the above fund will be elected and other matters in connection with it will be settled, the proceedings of which will be sent to the *Record* for publication.

All those medical men, especially Hospital Assistants, who were once MR. PILLAI's students, are therefore ear-

nestly requested to send their voluntary contributions towards the fund at an early date to the General Treasurer to be elected in the general meeting.

Yours, &c. V. S. ARMACHALAM PILLAI, *Secretary.*
Pillai Memorial Fund, Managing Committee.
MADRAS MEDICAL COLLEGE; 6th June 1895.

THE WOES OF HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—May I request the favor of your kindly taking into your kind consideration the following few lines and accord them your support as you think expedient in your esteemed journal?

Now-a-days steps are being taken to ameliorate the official status and title of the various higher grades of the medical service, both Indian and British; but poor Hospital Assistants are wholly ignored. They prove their work, though certified well deserving, meagre salaried and hardworking, and are recommended to be styled Sub-Assistant Surgeons by a Surgeon-General. Yet they are the same as they were originally. Lately the Apothecaries' designation was changed to that of Assistant Surgeons, and movements are being made to get the designation of Assistant Surgeons changed to that of Surgeons. Is not the designation of Hospital Assistants a misnomer for those holding executive charge? Years back the present Assistant Surgeons were called Sub-Assistant Surgeons, and the rank of Assistant Surgeon existed in the ranks of medical officers recruited from home; in other words, Netley Medical School. Men entering the Veterinary College have the same curriculum and scholastic education, yet they are considered graduates and are styled Veterinary Surgeons. It would be a great solace to the Hospital Assistants if their prospects and social position in the service is bettered.

Yours &c. NAROTAMDAS PARBHIDAS, H. A.,
In Medical charge, Kalol Dispensary.

KALOL, 6th March 1895.

AN INDIAN MEDICAL DEPARTMENT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Have you heard anything recently which would justify us in looking hopefully forward in the beginning of the next century to having the word "Subordinate" removed from the designation of our department? At present we are the Indian "Subordinate Medical Department", and it is reasonable to expect that where there is a subordinate, there must also be a superior, or else the differentiation is without reason. Now I defy any one to prove that the "Indian Medical Service" has been called anything but I. M. S. for about 8 or 10 years, and it is a thing quite of the past to hear it called the Indian Medical Department. If therefore it is admitted that this is so, i.e. that there is no Indian Medical Department composed solely of commissioned officers, I think it could be allowed that we be designated the Indian Medical Department (I mean Military Assistant Surgeons and Hospital Assistants) without the fear or possibility of a mistake being made, or the I. M. D. being mistaken for the I. M. S.

That our position is subordinate no one can be foolish enough to deny, and we have sufficient to remind us daily that we are so, without having to put it after our names whenever we have occasion to sign officially.

Is it true that the Government contemplate giving an extra couple of years before being retired compulsorily to men who have attained the age limit of fifty-five? There will be so many "special cases" that some of us need never hope to merit a "Star" unless we partake liberally of "Parr's life pills."

Yours &c., JOB.

HOSPITAL ASSISTANTS' QUALIFICATIONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With reference to V. S. P. A.'s letter in your issue of 1st May, I beg to state that Dr. Dallas's remarks, it seems, are applicable to the Dacca Medical School only.

In the Bombay Presidency Hospital Assistants have been trained in English ever since the opening of Schools at Ahmedabad, Poona, Hyderabad (Sindh) in 1878. The subjects taught in the Ahmedabad Medical School are as follows:—

(1) Anatomy; (2) Physiology; (3) Chemistry; (4) Materia Medica; (5) Medicine; (6) Surgery; (7) Midwifery; (8) Medical Jurisprudence.

The candidates have to produce a certificate of having finished the Anglo-Vernacular Standard V at least, and the Entrance examination is held by teachers in Dictation, English (reading and translation) Arithmetic and Geography.

During their school course they are examined by teachers assisted by assessors in the above-mentioned subjects.

When at school I was classmate with a number of students who had passed the matriculation.

Yours &c., A BOMBAY HOSPITAL ASSISTANT.

RAJKOT, 10th May 1895.

REVIEW.

THE CARE OF THE BABY: A MANUAL FOR MOTHERS AND NURSES. Containing practical directions for the management of infancy and childhood in health and in disease. By J. P. Crozer Griffith, M.D., Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania, &c., (Publisher: W. B. SAUNDERS, 925 Walnut Street, Philadelphia). Price \$1.50.

It has seldom fallen to our lot to peruse a work written in the compact, *chaty* and yet interesting and really instructive style as is this one from the pen of DR. GRIFFITH, who grapples with a huge and difficult subject in a truly masterful manner and in the small space of eleven chapters, distributed over 340 pages of clearly printed matter leads us step by step from the embryonic to the pubescent period of that little tyrant, BABY, whose manifold ailments and tribulations have severely overtaxed many a powerful mind are now.

Strictly avoiding altruisms, disproving many popular fallacies that have hitherto obtained in the guise of truths and keeping thoroughly up-to-date, DR. GRIFFITH combines brevity of detail with clearness of description without falling into technicalities, and lays the plot of his *chef-d'œuvre* of medical literature, under seven principal stages, in which he considers:—(1) The hygiene of pregnancy, how to calculate the probable date of confinement and to do, before the baby comes, the hundred-and-one things necessary to be done for the begetting of sturdy offspring. (2). The characteristics and growth of the mind and body of healthy infants. (3). Basking, Feeding and matters relative to a properly-conducted nursery to the development of *mens sanas in corpore sano*. (4). A concise *resumé* of the symptoms and management of the commonest diseases of childhood. (5). Ready methods of relief in cases of drowning, poisoning and many other accidents. (6). Special directions for the nursery and preventive management of infectious diseases, such as diphtheria, small-pox, &c., and (7) a copious appendix embracing dietary, remedies for local use and internal administration, and many valuable hints for easy avail by those mothers who through various circumstances are unable to have a physician constantly within a moment's call.

We are one with DR. GRIFFITH when he claims that he has endeavoured to make his statements plain yet scientifically accurate to be of service not only to mothers and nurses, but also to medical students and to those practitioners whose opportunities for observing children have been limited; for both the charming novelty and the excellence of his work lie in the simplicity of the language he adopts, and he is to be heartily congratulated upon the production of a useful *multum in parvo* which calms the mother's fears and saves the doctor many an unnecessary trudge by making her understand when it is absolutely necessary to send for a physician, and what she should do before he arrives so as to simplify his work and save her little one's life.

• Government Medical Gazettes.

GOVERNMENT OF INDIA.

Undermentioned Civil Asst. Surgns. of Punjab Provincial Establishment are promoted to grade of Uncoovenanted Med. Offr.

First grade Asst. Surgn. Chetan Shah, *Akhan Bahadur*, Honorary Asst. Surgn. to Viceroy;

First grade Asst. Surgn. Lala Bhagwan Das (1).

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

KENNEDY.—On the 18th June, at 178, Cromwell-road, South Kensington, the wife of Brig. Surgn. Lieut.-Col. Keegan, F.R.C.S., of a daughter.

DIMMOCK.—On the 6th July, at Mount Pleasant, Malabar Hill, the wife of Surgn.-Maj. H. Peers Dimmock, I. M. S., of a daughter.

PRICE.—On the 9th instant, at Mussoorie, the wife of Surgn. Lieut.-Col. Gordon Price, of a daughter.

DEATH.

COATES.—On the 10th July, in Calcutta, John Martin Coates, M.D., Brig. Surgn. Indian Medical Service. (Retired). Age 63 years.

NOTICES TO CORRESPONDENTS.

D. N. C. P. (Lucknow).—If you pass the "Entrance" of any Indian University, you can claim all your collegiate course certificates, and you will get them on payment (see *Medical Register and Directory of the Indian Empire*). All such certificates will be recognised by British corporations, and you may present yourself for your examinations on landing. Having secured your diplomas, you may compete at the next I. M. S. examination. For further information see *Directory* to be had of Manager, *I. M. R. Office*.

M. R. (Triplicane).—Your excellent paper will appear in an early number.

A Madras writes:—"Touching your comment on the 'Strychnine cure for snake-bite' in the *Record* of the 16th June, you will find an interesting article in the *Madras Mail* proving that it was practised in Malabar long before it was thought of by European doctors, vide Madras Surgeon General's Circular No. 14 of 7th June 1893, which warns against experiments on lower animals, and Circulars No. 60, 7th January 1891 and No. 1210, 23rd February 1893 contain the previous official directions. Yet experiments were undertaken at a vast expense of public time and money."

A Surgeon Major writes:—"I find in the Madras Surgeon General's Circular No. 14, 14th May 1893, that 12 copies of the *Indian Medical Gazette*, at an annual cost of Rs. 180, are purchased by the Madras Government for the benefit of its civil surgeons. Surely this is an unjustifiable waste of public money, and a cruel effort to crush the enterprise of such journals as the *Record* and the *Reporter*."

V. S. (Sinoga).—Saunders' Essentials and the books reviewed in the *Record* will suit you. Look up the Manager's advertisement in this issue.

P. V. R. R. (Kaikalar).—We have not the address of the Kuviraj you write about.

L. K. V. (Hati Mardan).—Have a little more patience. We think members will be very pleased with their certificates when they get them.

T. C. B. (Fort Govindpur).—We have your strolcher drawings. The cost of lithographing will be Rs. 40.

H. K. S. (Raiganj).—Your paper appears in this number.

J. J. S. P. (Calicut).—Many thanks, your paper will receive early attention.

M. B. K. (Bilgram).—Yes, wait a little.

M. J. (Vellore).—Write to Dr. Palpu of the Mysore Vaccine Depot, and he will gladly give you the information you need about vaccine.

B. H. N. (Ahmedabad).—Thanks, later on.

L. J. (Lucknow).—Your excellent paper will shortly appear. Many thanks.

K. A. (Dacca).—To get the M. D. of Brussels University you must possess fully qualifying British diplomas.

V. S. H. P. (Madras).—We think Dr. Dallas has been sufficiently answered. The doctor evidently refers

to some very poor material found in his district; while on a class, Hospital Assistants are daily proving themselves a capable and highly useful body of practitioners.

J. K. D. (Sultanpur).—Make an application to Government. There is no precedent on which your questions could be satisfactorily answered.

M. D. T. (Dhoraji).—See this issue.

M. J. P. (Jammalamadagh).—Your station has a frightfully long and unpronounceable name. If you possess an Indian degree you can claim exemption from all the junior examinations of the British Corporations and obtain a diploma by passing the senior exam.

C. F. P. (Melbourne).—In India the old "warrant" of Apothecaries was a diploma entitling its holder to practice medicine, as may be seen from the Bengal Army Regulations. This "warrant," however, was not a registrable diploma outside India. We think the new diplomas of our Medical Colleges would be acceptable as licences in the colonies and would be registrable. You should apply to the Government of India for an authoritative expression of opinion on the value of the old "warrant" as a diploma.

Several other contributors and correspondents will find attention in our next issue.

ORIGINAL ARTICLES.

CHOLERA AND ITS SPECIFIC FEVER.

By SURGEON-MAJOR PATRICK HEHIN, M.D., F.R.S.E.,
F.R.C.S.E., D.P.H., (Cantab.)

Lecturer on Medicine and Pathology, Hyderabad
Medical School.

THE specific fever theory now has been advocated several times by eminent authors during the last fifty years, but the evidence adduced hitherto has scarcely been sufficient to support the theory. OLDFHAM in 1872 aroused considerable attention by his chill theory of cholera; as did also Surgeon-Major ALEXANDER SMITH in the same year, with his malarial theory of cholera.

The theory that cholera is a pernicious or other form of malarial fever has been advocated for many years. This view was at one time employed as an argument against its being either contagious like small-pox or propagated from person to person as a specific fever.

It can scarcely be conceived that it could be in the waters examined, and yet one fails to discover it so repeatedly. But more than this, we have found it in the serous diarrhoea of certain cases of malarious fever, in simple diarrhoea and other cases. We have seen it frequently in cholera evacuations, but almost invariably in association with one or some other forms of bacilli; far more active than itself, and we have repeatedly expressed this opinion.

Those who have given any attention to the subject of the hæmatozoon which I discovered in the blood of cholera cases in June 1891, must have been struck with the remarkable similarity between it and the plasmodium malarie as met with in this country; and probably no one but experts would, at first sight, clearly define the differentiating characteristics between the two. Marked differences, however, do exist, especially as regards the rapidity with which the cholera parasite carries out its life-cycle; its considerably greater activity, and consequently its greater destructive power on the blood; the existence of well-defined flagellated structures which carry out an intra-cystic phase of development in the blood before being set free; probably the large quantity of toxins generated, &c., &c.

It is not my intention to burden the reader with a description of the hæmatozoon, but for the purposes of this note, it is necessary to state that the parasite is a protozoon of the new class created by LEUCKART, viz., *sporozoa*; that it is polymorphic, and that from its development in the embryonic spore-stage to that of maturation into free flagellated plasmodia on the others, it exhibits several forms, which are highly interesting.

As in the case of ague, the development and setting free of intra-cystic spores is an important phase in the life-cycle of the hæmatozoon of cholera, and I believe that it is during the process of sporulation that the poison which gives rise to the symptoms of cholera is developed. I further believe it to be possible to abstract a tox-albumen from the serum of cholera cases which would create the symptoms characteristic of that disease. This aspect of the question is the subject of another paper which will appear shortly.

The process of evolution in the life-history of this hæmatozoon appears to me to be both distinct and unequivocal: (1) formation of cystic structures; (2) spore formation; (3) liberation of spores; (4) development of intra-cystic flagellus; (5) free flagella, &c. Of these (2) and (3) are always visible; (5) is seen in about 80 per cent; (4) in about 15, and (5) in about 6 per cent. of cases. One single observation in which (5) is met with, will remove all doubt, and I feel sure that those who have averted on my description of these flagella, will be the first to admit the significance of this discovery when they have the opportunity of making this observation.

The effect of the poison should, according to this view, be limited only by the number of organisms, and the extent of sporulation, which latter determines the quantity of the poison generated at any one time. But on the other hand, after the elimination of the poison, there is a rapid return to health.

It may be thought that one has rushed to conclusions on inadequate data, but the following considerations demonstrate that the position I have taken up may be based on a sound physiological and pathological basis.

It is a well known physiological fact that the vessels of the skin are capable of adapting themselves to enormous changes in calibre. It is further known that this is due entirely to their comparatively large amount of elastic and muscular tissue and its well developed vaso-motor nerves. In this way we are not only able to explain many of the phenomena noticed in health, but many of these in disease.

But other factors are also at work in producing anæmia, viz., qualitative and quantitative changes in the circulating blood. Now when an active constriction occurs in the cutaneous vessels, a peculiar sensation is experienced, and locally the skin is felt to be less succulent and cooler. If the normal tonus varies, the temperature may not alter, and the volume of blood remains *status quo*. This gives a broad basis upon which to regulate the circulation of the skin. Changes in quantity arise from deficiency of red or increase of white corpuscles, or a minimum of both these conditions. The former factor is well seen in true chlorosis, athrepsia and mal-assimilation, both of which may arise from a dozen different maladies; in lasting febrile diseases, in the various states producing pseudo-leucocythæmia; but in true leucocythæmia, there is also an exaggeration of the number of white blood cells, relative and absolute, in certain forms of anæmia, and in the cachexia arising from such conditions as cancer, tuberculosis, &c., whilst there is at the same time a deficiency of hæmoglobin, there is likewise a diminution in the total quantity of the blood. In these states therefore we have a complexity of phenomena as regards the circulation of the skin, the main factors being an altered condition of the calibre of the vessel to accommodate itself to the decreased volume of blood circulating, a change of color in the blood itself due to a serious modification in the quality of the blood. The most manifest form of this variety of anæmia is seen in wounds which have bled freely in cases of post-partum hæmorrhage, in the hæmorrhages from internal piles, ulceration of the bowels, and that

from persons affected with the anchylostoma duodenale^o &c., &c.

In cholera in fair-skinned people, we have the characteristic bluish-gray or "ashy" hue of the skin, which is also brought about by two factors: (1) a cyanosis of the blood itself which becomes progressively greater as the rapidity of the blood-flow lessens, and (2) universal constriction of the cutaneous vessels.

It is usually stated that the fall of external temperature in cholera and the rigid contraction of the vessels of the skin is brought about by a serious alteration in the quantity flowing through it at any one time—therefore we have a condition comparable, if not identical, with cases of isolated anemia in which no modification of quality arises. This may involve all the skin or only a part of it. If the surface of the whole body is anemic, the entire circulation or the general nervous system must be affected.

The most marked and important example of cutaneous constriction is seen in the rigors of the incipient stage of the acute specific fevers. Here we know or believe, that there is a *materia morbi* circulating in the blood supplying the vaso-motor nerve centres, which stimulates them, and gives rise to rigid constriction of the peripheral vessels. If the rigors are severe, the vessels of the superficial muscles are also affected, and even those of the internal organs become abnormally full. Hence the temperature of the surface falls, and that of the deeper parts of the body rises.

Warmth, covering of the body, &c., which prevents loss of heat, may particularly overcome the tonic constriction by paralysing the vessels. We daily see in India that with a terrible fit of shivering the temperature in the covered axilla is rising and continues to do so, till it reaches its acme. On the other hand, cold accelerates the rigor, shewing that the tone of the vessels, in the interval between the rigors, is really raised, and only kept in check by the greater warmth of the blood and the active surface loss.

Certain poisons as ergot and strychnine contract the blood vessels, tonically, although it is not the arterial spasm of rigor, and the pallor after acute poisoning with alcohol is similarly produced by the products of decomposition. It is not a slight irritation which reflexly or directly produces a general cutaneous anemia, but general pathological circumstances, which modify profoundly the whole constriction. This we understand at once when we remember that the natural constriction is very great, and that the vasomotor nerves must be greatly stimulated to cause visible pallor and sensible cold.

Cold is the most frequent cause of additional tone in the cutaneous vessels, but to cause this effect, cold must be considerable, such as is caused by ice bathing or sponging.

If the difference in temperature between the external air and the body be but small, the temporary arterial spasm of health is followed by a relaxation of the vessels, and the heat may continue to be lost. This is the case when the

^oIn people under 50, especially those with a fair supply of subcutaneous fat, anemia usually causes the skin to assume a peculiar yellowish semi-transparent, waxy appearance. This arises from the operation of two factors, (1) the regulation of the calibre of the vessels by the action of the vaso-motor nerves—an adaptive process created by a conservative natural action—and (2) absorption of the tissue fluids by the veins and lymphatics.

body is submitted to a cold stream of air or immersed in a moderately cold bath and subsequently removed.

In the matter now before us, we are concerned primarily with the vasomotor factor of the blood vessels of the surface, and the facts so far elucidated, point to a vigorous contraction of the arterials of the cutaneous superficial muscles, sometimes the deeper muscles, and even the internal organs.

In almost every case of cholera, the blood in the deeper parts is considerably above the normal temperature. Those who have seen much cholera know that some cases begin with a high surface temperature, which gradually goes down. But in most cases, if we were to force the blood into the surface as may be done by the transfusion of differentiated blood or saline solution, we should find that the temperature would rise more or less suddenly. As stated, the operation of transfusion shews this at once.

On five separate occasions we have had cases which indicate that the internal temperature is considerably above that in the superficial parts—a fact which points to the effect of the poison on the vasomotor system.

It would seem indeed that the first effect of the poison is to bring about a constriction of the superficial arterioles, so that there is a regurgitation inwards to the splanchnic area. Indeed, we have here the effect on a large scale pathologically, which follows the stimulation of the peripheral end of the divided superior cervical ganglion of the symptom on one side in the rabbit's ear and side of face.

In cholera there is a general paralytic state of the vessels of the splanchnic area, which produces active congestion of the mucous membrane of the alimentary canal, shewn by the effusion into the bowel, sudden diarrhoea and vomiting. In all probability this effect is the same in kind, but vastly more intense and prolonged in its effect than that which in malarial fever gives rise to the rigors of ague.

Further, as in ague, it may possibly be due to the poisonous substance produced during the process of sporulation. As in ague, the effect is limited only by the number of organisms present at one time, but in cholera the process is more or less constant, and not intermittent. We should remember, however, that Sir JOHN SIMON states the condition of the circulatory system in collapse, and Dr. JOHNSON'S doctrine of the dependence of that state on spasmodic closure of the minute pulmonary arteries are doctrines which do not necessarily involve an acceptance of the eliminative treatment of cholera, nor presuppose any belief that cholera begins as a blood-disease. It is important that the different questions should not be jumbled together as one; particularly important now, since the notion of a primary blood poison in cholera seems to be a question still at issue." Again SIMON writes: "In the present state of our knowledge I do not find it proven nor do I see any theoretical convenience in taking for granted that cholera begins as an active blood change capable of producing primary collapse. The facts, so far as I know them, can all be reconciled with the belief that cholera begins as a bowel disease, producible by direct contagion without even a passive intervention of the blood

and that all anaphoretic phenomena of the disease are supererogatory phenomena. That, so far as they are facts of cardiac paralysis and arterial contraction, they may be attributed to nervous sympathy between the bowels and circulatory system, without reference to the greater or less humoral effect of the coincident flux from the bowels, is at present a tenable view. At the same time, I hesitate to accept as proven that cholera collapse is independent of humoral sympathy. In questioning the fact of a primary blood poisoning in cholera, I of course, do not intend to deny that the blood during cholera is poisoned. From our earliest knowledge of the disease, it has been on record that, when pregnant women have cholera, the intra-uterine offspring almost invariably dies; and more recently, in proportion as the anatomy of the disease has got to be better studied, cases have accumulated, giving detailed evidence in support of an opinion which had from the first been entertained, that the infant in such cases dies of true choleraic infection. Waiving particular reference to earlier cases of this sort for which see, for instance, *Phabus*, 1833, *op. cit.* 51,^o and *Burl*, 1866.

Such is the nature of cholera according to the observations of SIMON, PARKES, WILLIAM ROBERTSON, SCHMIDT, NEIMEYER, JOHNSON, and SIR THOMAS WATSON, and thus "an early theory of the nature of this disease has received the support of the best physicians and chemists of the day—namely that the blood, if not the primary seat of the disease, becomes eventually contaminated by the action of a specific poison."

At the International Medical Conference on Cholera, which met during Easter of 1867, at Weimar and which Mr. SIMON attended, Professor HALLIER of Jena, and Dr. BARY of Halle (two of the leading mycologists of Germany) were associated with Drs. THOME and KLOB in making, in common with them, a statement and an appreciation of the facts which had been observed and which are in substance that—"Both observers find in cholera evacuations, and in the intestinal mucus of the dead body, definite organic structures, consisting of excessively fine granules, clustered together more or less densely, in the interspaces of a jelly which surrounds them. The granules divide and sub-divide themselves, and form beaded threads, which interlace in immense numbers into small masses in the mucus. The further development of these organisms has been determined by THOME and HALLIER. By sowing or cultivating them these observers have got, after some time, larger round cell-like bodies, which rapidly multiplied, and also abundant filamentous fungi (cylindro tenium), on which grew cylindrical spores capable of developing again into filamentous forms (Ninth Health Report of the City of London by Mr. SIMON, p. 31). In 1849 the question of fungi in cholera stools was repeatedly discussed on the repeated observations of several independent observers; but the objects then described do not seem capable of precise identification, or as being exactly the same as those now described. It would appear that BOEHM in 1838 described "the whole extent of the intestine as teeming with

a vegetation of micro-fungi; that innumerable round and oval, or more joined end to end, as links of a chain, and these chainlets sometimes branching; that such forms are held together, in mucous floccules, and come best to light when liquor potasse is used, that within the small intestine they are often so numerous that not the smallest specimen will fail to shew numbers of roundish fungi forms amid the debris of epithelium."

"(1). That no cysts exist in choleraic discharges which are not found under other conditions. (2). That cysts or "sporangia" of fungi are but very rarely found under any circumstances in alvine discharges. (3). That no special fungus has been developed in cholera stools, the fungus described by HALLIER being certainly not confined to such stools. (4). That the still and active conditions of the observed animalcules are not peculiar to this disease but may be developed in nitrogenous material even outside the body. (5). That the flakes and corpuscles in rice-water stools do not consist of epithelium, nor of its debris, but that their formation appears to depend upon the effusion of blood-plasma; and that the peculiar bodies of PARKES found therewith correspond very closely in their microscopic and chemical characters, as well as in their manifestations of vitality, to the corpuscles which are known to form in such fluid these are generally to a greater or less degree, associated with blood cells even when the presence of such is not suspected, especially as the disease tends towards a fatal termination, when the latter have been frequently seen to replace the former altogether; and (6) that no sufficient evidence exists for considering that vibrios, and such like organisms, prevail to a greater extent in the discharges from persons affected with cholera than in the discharges of other persons diseased or healthy, and monads (micrococci) may not be peculiar in their nature (for these do vary), and may not be the product of a peculiar combination of circumstances able to give origin to peculiar phenomena in predisposed persons—is not proven. Dr. MACNAMARA also asserts his conviction, after a long and attentive study of the subject, that fungi peculiar to cholera dejecta have not yet been discovered; that no doubt fungoid growths appear in this as in other nitrogenous matters undergoing decomposition, notably the *oidium lactis* and *mucor mucosus*; but neither are peculiar to decomposing cholera dejecta. Moreover, he desires particularly to affirm, that neither these nor any other fungoid growths can be discovered in fresh cholera stools. The more recent the specimen the clearer this fact appears. Dr. MACNAMARA has examined the contents of the intestinal canal for the appearance of mycelial threads or sporangia, and even after protracted collapse, has absolutely failed in numerous instances, in detecting any characteristic elements of the kind, and he states that he is reluctantly compelled to abandon his faith in the existence of any such growth. So far, therefore as fungi are concerned in the spread of cholera, I am satisfied that we have no grounds for such a belief. In the blood also there is a total absence of bacteria, fungi, or other extraneous bodies; but a great abundance of white blood cells, in a state of great activity, or of bodies which cannot be distinguished from the white blood cells. The red corpuscles have also

* Among the cases given in Phosburn's work is one where the infant was not actually born dead, but died an hour afterwards with all the symptoms of the epidemic disease."

been shown to be peculiarly different at their ends. The blood loses water, albumen, and salts, and is incapable of passing the capillaries with its usual freedom. It retains most of its coloring matter in its normal chemical composition, and Dr. THUDICHUM's observation led to the conclusion that any fermentation of the blood in the manner in which the intestinal contents are fermented, was very improbable. The blood absorbs water from the tissues; and there is no chemical evidence of any special cholera poison in the blood. The epithelium of the minor surface of the blood-vessels becomes detached and mixes with the blood, and the blood adheres to the blood vessels with great pertinacity. The secretion of bile is completely arrested, and in extreme cases a clear white fluid percolates through the hepatic ducts, free from bile, coloring matter and albumen. It seems to be simply water with a trace of alkali and a vestige of mucus. In some instances the fluid is colored, but contains no bile acids. The bile ducts shed their epithelium.

"They are always alkaline, consisting of a watery gruel or cream-like fluid, composed of thinner and thicker portions. Its consistence varies according to the varying quantity of its component parts. The thicker portions are flaky, stringy, curdy or clotted. When first passed, the rice-water evacuations soon separate into portions, the flocculent curdy matter sinking to the bottom of the glass or vessel in which it is contained, leaving a whitish fluid above. This separation of the material into two parts takes place rapidly in many instances, say in from one to three hours, and is evidence of the severity of the disease; for if the more solid matter of the dejecta collects in the lower part of the fluid very speedily, it indicates the complete death and disintegration of the organic matter. On the other hand, if the separation of the fluid and more solid components of the rice-water product takes place slowly, it is on account of the evacuation containing a considerable quantity of comparatively healthy mucus, and the case so far, allows of a more favorable prognosis. The flocculent matter of the stools is composed of epithelial cells, and the mucous lining of the intestinal canal in various stages of decomposition, but the perfectly fresh dejecta in the active stages of the disease contain no vibriones. Towards the end of collapse, when the evacuations are passed less frequently (probably remaining in the intestine for some hours) vibriones may be seen in the fluid immediately after it is passed."

On the basis of all the pathological phenomena and clinical data, the following seven stages of cholera may be distinguished:—(1) Fœcal diarrhoea; (2) choleraic diarrhoea and vomiting, quick sinking of temperature; leading to (3) asphyxia or collapse, in which the lowest temperature is reached; (4) reaction, which may be defined as the cessation of collapse and the beginning of the re-establishment of the suppressed functions; (5) torpid stage, or secondary period of algide stage, in which (reaction notwithstanding), the temperature remains below the lower normal limits, and then gradually or suddenly, rises to the normal average; (6) tepid stage, in which, during continued reaction, the temperature rises

to its normal or upper limits, more rarely somewhat above; (7) the febrile stage is only reached in cases where the entire algide stage has been very long, or where there are complications or secondary lesions arising out of the choleraic process. Reaction does not always terminate the algide stage. For although, from the moment of the beginning of reaction, the temperature rises somewhat in most cases, in the worst cases it does not reach the lower limits of normal fluctuation. The algide stage is evidently continued into the state of reaction, and the tepid stage is the result only of continued reaction. Reaction begins mostly with absorption from the intestinal canal within thirty-six hours from collapse, possibly also with some actual sorptions. It is not unreasonable to infer that, as in ague, the administration of quinine is of very little use after the effects of the poison produced by sporulation are well established. In cholera we have the additional reason for its decreased usefulness in that it is difficult to get it into the circulation during the collapse. A trial of this method this year failed to a large extent, possibly because of the large number of cases not seen till the stage of collapse was well advanced.

We can explain this on rational grounds—the quinine does not affect the spore formation once it has begun, but it can prevent it altogether. Hence the rule of giving it *at least four hours before the expected attack*. We have notes of over 1,000 cases in which we checked malarial fever by acting up to this rule. If the analogy holds good, there must often be no time in cholera for the quinine to act on the process until the evil is too far advanced.

I do not trust to the access of the alkaloid to the blood by its administration through one passage only—it is given by the mouth, by the rectum and by the hypodermic method. If this line of treatment is to be followed, no time is to be lost, for what is chiefly necessary is to get 30 or 40 grains of the drug into the system as speedily as possible, in fact we are to act on the same principle as if we were treating a case of malarial fever in which sporulation is continuous.

The process of sporulation is that which manufactures the poison in malaria and by analogy in cholera also. We cannot affect sporulation that is on, or which is in a stage preparatory to the setting free of spores, but we can check the commencement of sporulation, and that is I believe how quinine appears to act. It is a well-known fact that it is useless to give quinine during the pyrexia, or later than two hours before the fever comes on.

There are, of course, many cases in which cholera has been proved to be caused by the consumption of water polluted with rice-watery evacuations from cholera cases. But there have been many opposed to such a belief. CHEVREUS stated that no one had proved to his satisfaction that cholera stools contained a specific poison capable of propagating cholera to those who swallow it. He also states a fact often forgotten, viz., that nearly all Indian authorities who believe that cholera is communicable by dejecta, judge from their experience of epidemic cholera in the North-West Provinces, whereas receiving all who have long worked in Lower Bengal, the home or endemic area of cholera, doubt that this disease is at all communicable from man to man.

Dr. CURRIE further states that he bases the following remarks upon facts that have come under his own observation, or within his knowledge and experience:—

(1) If a strong epidemic wave rise among us, its destructive effects will not be under control, for (2) whatever treatment may be adopted, a very large percentage of those first attacked will probably die.

(3) In cholera outbreaks, he who enters the epidemic or endemic area encounters special danger.

(4) The incidence of cholera will always be heaviest upon the most insanitary localities. It is dangerous to travel in the cholera area. Those who are well lodged and in comfortable circumstances have a great prospect of escape if they remain.

There is little hope that the use of remedies given by the mouth are likely to be of any avail during the stage of collapse. Such treatment as is to be of avail must be given in the early stage—that of diarrhoea. If we see the cases at this stage, we can, I believe, reduce the mortality to below 20 per cent., and this we can do by the use of large doses of quinine.

In the year 1883 Dr. BLANC^o wrote an important paper on the subject of pernicious malarial fevers, and stated then what I now repeat, that in India the subject of pernicious malarial fevers has not received a tithe of the attention their great importance and frequency deserves. When we consider the fact that true Asiatic cholera maligna is much like one of the varieties of pernicious fever, this fact may be recognised.

Indeed, some authors have gone so far as to declare cholera to be a type of malarious fever, whilst others have limited this form under the name *malarious cholera*, to a particular variety of Asiatic cholera. The clinical characters of pernicious fevers are intermittency, whilst the intermission is marked by some symptoms of the pernicious attack which are enough in many instances to render the diagnosis doubtful.

In the scientific world of to-day, it is considered by many to be heretical to utter a single word against the doctrines of KOCH in regard to the ætiological relations of cholera; indeed, it would seem that his very statement in this respect is inviolable, and will remain so to the end of the chapter. We, however, have had a great deal of experience with cholera, and we have spent years in investigating its ætiology, and we are forced to express the conviction that we believe that the comma bacillus is altogether inadequate to produce such a profound change in the system as that brought about in cholera. We believe, on the other hand, that the organism is one which invades the system as a whole, and not the alimentary tract only. We further believe that if the parasitic organism we have discovered is not the cause of cholera, the cause remains to be discovered; and that discovery will take place within a very limited period—possibly before the close of the present century. Lastly, we would beg to state that in making the above remarks, we do not wish it to be thought that we are wanting in respect or admiration for the immortal ROBERT KOCH—far from it. We have the most profound reverence for his work; his perseverance and modesty; and lastly

we believe, that the work which he and PASTEUR have done has been the cause of a complete revolution in the treatment of specific and communicable diseases in man and the lower animals.

As a rule, I see one or more cases of cholera almost every day of the year; at least since January last there has only been an interval of sixteen days in which no cases occurred in the municipal township, of which I am the Health Officer. I have on several occasions this year, proved beyond all equivocation that certain wells were poisoned with cholera virus, for in several isolated outbreaks occurring amongst people who used the water of such wells, on the closure of the wells, and the supply of filtered hydrant water, the outbreaks ceased in every case.

We have no doubt but that were we able to carry on original investigations on the plains of India, some of the large number of medical officers who now devote themselves to the study of bacteriology would have long since proved the absolute absence of any ætiological relations between the comma bacillus and cholera.

There is one important fact associated with the comma bacillus: its presence enables us in almost all cases to diagnose cholera at once—about this we have no doubt. This rule, however, is not absolute, for we have met with at least two cases of cholera, possibly a third, in which it was absent, whilst we have also found it in cases in which the idea of cholera could not arise.

During the Commission that came out to India in 1885, Drs. KLEIN and H. GIBBES, after thoroughly investigating the subject, gave their opinion against it, and KLEIN is probably one of the greatest microscopists of the day.

Again D. D. CUNNINGHAM, who has done more original work in connection with cholera than any man living, does not believe in ætiological relations of the comma bacillus; in fact, he has himself described eight different varieties of this bacillus with distinct characters, and no doubt there are more.

—:O:—

LEPROSY WITH SPECIAL REFERENCE TO KASHMIR.*

By A. MITRA, L.R.C.P., L.R.C.S. (Edin.)

Chief Medical Officer, Kashmir.

THE valley of Kashmir has a population of 949,041, of which 883,252 are Muhammedans and 65,789 Hindus. The inhabitants of the valley proper are distinct from the people living on the slopes of the mountains around. Rice forms the staple food of the Kashmiris, which they eat twice daily with boiled vegetables. Meat is also eaten, but daily only by the better classes. Fish, fresh or dried, is freely used. The majority of the people are agriculturists. The boatmen form a large bulk of the population, and they eat more fish than others. The boatmen on the Wular lake live principally on fish, which they cook in the form of pulp and eat with salt. Syphilitic diseases are the scourge of Kashmir. The rate of infant mortality is very high on account of syphilitic diseases. Syphilis is so widespread among all classes of people,

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

that it has almost assumed the magnitude of a national calamity. The habits of life of the people are very unclean, and there is an utter disregard of public and private hygiene. Among the people I have described, leprosy is a rare disease. A census of lepers was taken in 1890. It was taken unassisted by medical officers, and therefore, probably included many cases of diseases other than leprosy, and excluded many cases of true leprosy in the incipient stage. It also omitted to record the nationality. Many foreigners might have been entered in that list. It showed the total number of lepers to have been 404; male 168, female 84, Hindus 4 and Muhammedans 198. I have not met with more than 30 real Kashmiri lepers. What may be the cause of this comparative immunity of Kashmir from leprosy? It is a strange fact that the Kashmiris are almost surrounded by leper neighbours among whom the disease must have been prevalent for a long time. In spite of this, the Kashmiris living in the valley have been free from the disease. The slopes of the hills between the flat ground and the limits of snow on the Pir Panjal ranges of the Himalayas are a mixture of cultivating and grazing grounds and forest of cedar and pine. These slopes are inhabited by a people called Goojars or cowherds who keep buffaloes and cows. In winter the Goojars live at the foot of the hills and in summer in temporary huts on the mountains. Their food is Indian corn and wheat, and they also use milk and milk products abundantly. They live in ill-ventilated houses, often overcrowded with men and cattle. They are not well clothed. They are not beef-eaters, but occasionally indulge in buffalo meat. Among these Goojars leprosy is a common disease. Lepers are not allowed to mix freely in society in the Goojar country, and a leper has to take his food apart even from his nearest relatives. The lepers, therefore, usually come to Kashmir or go to adjoining districts in the Punjab for means of livelihood. The Punjab is very hot in summer and the Punjabi lepers find that during the hot season eruptions frequently break into ulcers which heal in the temperate climate of Kashmir. So annually, a large number of Punjabi lepers flock into Kashmir during summer and live on the charity of the Kashmiris.

Heredity.—Heredity is no doubt an important factor in the causation of leprosy. Such is the opinion I have found after careful enquiry among Goojar lepers. I have seen a family with three generations of lepers. Of course, in many cases, heredity could not easily be traced, but in all such cases unsatisfactory answers were elicited. To the question "Was your grandfather a leper?" the answer was "I cannot say as he died before I was born." (!) There are no doubt cases of acquisition, but among the Goojars, inheritance plays a more important part than acquisition.

Is leprosy contagious? I saw one instance of a wife acquiring leprosy from an affected husband. Five years after marriage the husband showed symptoms of leprosy; after another five years the wife became affected. When I saw the couple they had no children. I have seen in a family the grandmother, an old woman, suffering from a very bad type of ulcerative leprosy attended

with foetid discharge and sloughing. The affectionate daughters and grand-daughters nursed her without the slightest thought of themselves. The old woman died five years ago. None in the family is affected. From my experience I can cite no instance in which the disease was transmitted from a leper to any member of his family with whom he lived together and mixed closely in social life, except the one in which the wife was affected.

Though leprosy is not common among the Kashmiris, still Kashmir is resorted to by a large number of lepers for its climate and means of livelihood. These lepers freely mix with the people, sit, eat, and pray with them (lepers are usually found at the doors of Moslem prayer-houses), and no precaution against contagion is thought of, still the disease does not spread among the Kashmiris. In India and in the northern hilly countries we find lepers freely mixing with their relatives, walking about in public streets; leprosy husbands having progeny from their unaffected wives; in short, the public is exposed to the disease in every conceivable way. Does it extend in the proportion it ought if contagion by contact be admitted?

How then is leprosy transmitted? Accepting the bacillar theory of the disease, one could easily imagine that it may be passed from one individual to another by various means by which any other disease depending on germs, such as tuberculosis, may be transmitted.

Of course, contagion by inoculation is possible, and often takes place in various ways. All the different ways by which syphilis can be passed from one individual to another extra-genitally, hold good for leprosy. In India people usually have their feet and skin bare, and therefore there is every likelihood of inoculation. The question of compulsory segregation can only come when it is finally proved that leprosy is contagious by contact. It is no doubt a loathsome disease, with public feeling strongly against it. The word "leper" is synonymous with everything that is abhorrent. Whether this public opinion is right or wrong, we as scientific observers should lay aside our prepossessions, and steer clear of preconceived notions and prejudices. Then again, it is difficult to conceive how segregation can be complete, even if it were tried for experimental purposes. Is it always easy to recognize the disease in its early stages? Is it not very common that early stages continue for a prolonged period, during which the contagion, if any, will be equally communicable as in later stages? Does it not sometimes baffle even experienced physicians to recognize and distinguish the disease from several forms of skin diseases and neuroses? Will not the rich try to evade, and the poor be submitted to unnecessary hardships?

It is not easy to conceive how isolation can be humanely carried out, and how it can be complete, regular and perfect; and, unless it is so, its very object is defeated. I think however, that unless proved by fresh observations and experience, our present knowledge of the disease does not justify belief in contagion by contact.

However much we may differ in this and similar points, I have no hesitation in saying that free leper

asylums for the care of lepers all over the country is an absolute necessity for preventing the spread of the disease. Such asylums should be made attractive by clean hygienic surroundings, substantial and wholesome diet, recreation and diversion, and medical treatment and comforts. Then not only the poor but many of the middle class will voluntarily flock into them. In such asylums, not only caste distinction but also that of social position of the inmates should be observed. Those who are willing or can afford to pay will be paying inmates. Every District Board, which maintains a dispensary, should maintain a leper asylum also. By this means, segregation will be the practical result without raising any clamour or opposition. I believe that to the improvement of general sanitation and habits of life of the people, we are to look for the extermination of the disease more than to any measures of compulsory isolation. I also think that "arm to arm" vaccination is extremely dangerous in a country where leprosy is prevalent.

Hutchinson's fish theory.—The Goojars do not get any fish. I have for some time always asked lepers if they were fish-eaters, and in the majority of instances the reply was in the negative. The theory is untenable in India, where we do not find the disease more prevalent among fish-eating people than among abstainers of such food, as the *Vaimabs*. High class Hindu widows are strictly prohibited from taking fish, but I have seen several cases of leprosy among them. The Kashmiris, among whom leprosy is rare, are fish eating, fresh, dried and salted. But the positive fact that leprosy is common among Goojars, completely disproves the fish theory.

Treatment.—In the treatment of leprosy, I have given trial to chalmugra oil, gurjon oil, neem (*azadirachta indica*), both internally and locally. I have also tried arsenic, phosphate of soda, mudhar (*calotropis gigantea*). In the ulcerative stage local applications of gurjon oil, or neem oil, prove of some value in healing and checking factor. Creolin or izar does the same. My experience is that none of the above remedies possesses any power in arresting the disease.

In the anæsthetic variety I have practised nerve-stretching in over a hundred cases. I am of opinion that in the early stage, nerve-stretching produces some satisfactory result. The tracts, supplied by the nerve or nerves stretched, regain sensation partly, trophic ulcers heal rapidly, and the general health of the patient, improves; but these results are not lasting. A patient whose nerve has been stretched and who has left the hospital with his condition improved, encouraged by the previous result, usually comes back for treatment with the same condition as before, and probably with lesions spread over other parts, such as the face. This treatment can therefore, be safely called a palliative one, applicable in certain classes of the disease in its incipient stage.

I have never seen a leper cured, but, under strict medical care, he can be made comparatively free from his troubles and his sufferings can be alleviated.

THE CONTAGIOUS DISEASES' ACTS IN INDIA : THEIR COMPLETE FAILURE, PROVED FROM AUTHENTIC RETURNS.

By W. C. MARGE.

Calcutta.

If it were true that the consequences of immorality could be prevented by physical arrangements, without any moral reform in the mind of the immoral man, all moral law would be extinguished, because it would be stultified by facts; for it would then only remain for people bent on self-indulgence to choose their vice and find out the method of satisfying it in safety.

No intelligent opponent of the Contagious Diseases' Acts has ever objected to the tenderest care being taken of any victims of venereal disease, male or female. On the contrary, the most effective treatment of all such sufferers has always been advocated with a view to their restoration to a virtuous life after the cure of the bodily suffering. What has been objected to is the compulsory subjection of woman alone to personal restraint, usually including gross outrage, not with a view to their reform and removal from a career of vice, but with a deliberate purpose of physically preparing them to continue the practice of vice, while their male partners in immorality are left entirely free, even when in a diseased condition, to indulge in vice and thus spread the very disease which a solemn pretence is made of wishing and trying to suppress. Is not this sacrificing the liberty of women to the license of men? If the system of so-called "Protection" introduced by the Acts had ever succeeded anywhere, its success would for the first time in human history have not only shown morality and science to be in deadly conflict, but would also have resulted in the abolition of morality. A chain is no stronger than its weakest link, and a practical world could not afford to be governed by a theory of ethics which had been broken down in practice.

To prove that this system of "Protection" has not only not succeeded in India, where it has been on trial for nearly twenty-five years, openly for the greater part of that time, and secretly for the last three of these years, but has completely failed, is the object of this paper, to which the earnest and careful attention of all honest men is solicited.

Its figures are all taken from authenticated official sources, to which reference is in every case made.

The history of medical effort to suppress venereal disease in the British Army in India divides itself into three periods:—

(1) The period before the introduction of the C. D. Acts.

(2) The period of the working of these Acts; and

(3) The period following the abolition of these Acts.

I. The following extract from para. 14 of the Memorandum of the British Army Sanitary Commission on the report of the Sanitary Commissioner with the Government of India for 1889—dated London, War Office, August 28th, 1891—contains the verdict of the highest military-medical in the British Empire, which is finally responsible

for the sanitary arrangements of the British Army, on the first of these three periods:—

"These (Lock) Hospitals existed for 18 years, from 1867 to 1884 inclusive. The figures for the individual years 1870-79 are not given, but it appears that during these ten years the average annual admissions from venereal disease were : for Bengal 209, Madras 189. Bombay 292 ; and all India 294. *Instead of a decrease there had been a marked rise, amounting roughly to about one-third in each Army.* And what is still more worthy of notice is that *the statistics of 1866, before lock hospitals were established, are much more favorable than those of 1884, when these hospitals had been at work for 18 years.* The figures of 1866, apparently, are not available for Bombay ; but for Bengal they give 217 cases per thousand in 1866, and 290 in 1884 ; for Madras 236 in 1866, and 300 in 1884 ; or, if comparison be confined to the more serious forms of primary disease, we find that in Bengal the rates rose from 64 in 1866 to 86 in 1884, and in Madras from 30 in 1866 to 101 in 1884."

The outstanding facts of this declaration are, first, that, as regards a particular period of 10 years from 1870 to 1879, during which the Acts were in full operation, there was not only no decrease in disease, but a "marked rise ;" and second that, as regards the entire period of 18 years during which the Acts were enforced, the prevalence of disease, as shewn in hospital admissions, and whether as respects secondary or primary disease, was worse at the end of the period than before the Acts were introduced.

The figures for the individual years from 1870 to 1879, which were omitted from the Indian Sanitary Commissioner's Report for 1889, will be given further on together with the figures for all the intervening years down to 1885 ; and they will shew that, with slight fluctuations, there has been a progressive increase in disease during the whole period of the operation of the Acts ; but the point which unbiassed minds will fasten on at this stage is that, in the final judgment of the British Army Sanitary Commission, the British Army in India fared better before the introduction of the Acts than after it.

To prevent any charge of unfairness, or of mutilating extracts, a further quotation is here made from the above para. 14 of the same document ; though it will best be fully considered later on. It is this :—

"The (Indian) Sanitary Commissioner would explain these remarkable results by 'the greater youth and inexperience of the soldier, the smaller proportion of married men, and the more frequent and extended movement of troops ;' and it is to be borne in mind that the short service system came into force in 1870, and has been in operation since that time. Whatever degree of importance however, is to be attached to these causes of increase, the fact remains that the expectation of benefit to be derived from lock hospitals when they were established was very far from being fulfilled."

The true character of the boast that the Acts were preventive, and that disease could be entirely suppressed under them, is here clearly revealed. What the Indian Army Sanitary Commissioner evidently contends, is that the Acts would have proved preventive and disease would

have been suppressed, if soldiers had been older and married, and there had been less frequent and less extensive troop movements. This interesting speculation, which certainly reveals more of the originality of the Indian Sanitary Commissioner than of the facts of disease in the Army, will be presently considered. The facts meanwhile are, that the Army fared better before the Acts than during their incidence, and that the benefit expected from them was not realised.

II. In considering the second period, it is necessary to go to the late Dr. BARCLAY's note on the "Experimental closure of several Indian Lock Hospitals during 1885," because it was published authoritatively in 1886 by the Indian Sanitary Commissioner as the unanswerable defence of the Acts by the Indian Medical Department, and because—though strangely suppressing some striking figures, which have been otherwise obtained, and are given below—it contains several groupings of figures which are not otherwise accessible to the public.

As this note of Dr. BARCLAY's was considered a masterpiece of scientific reasoning, and has often been incorrectly referred to as establishing beyond question the prophylactic virtues of the Acts, it is only fair, before examining Dr. BARCLAY's methods of reasoning, to realise plainly the basis from which he starts, and the limitations which he acknowledges. He says:—

"The utility of any special measures against these diseases had come of late years to be greatly doubted, and this especially because, in spite of the continued operations of certain laws enacted in 1864, to suppress and, if possible, extirpate them, *these diseases have given rise to progressively higher admission rates of late years.* The rise in the admission rates, especially since 1877, led many to believe that the futility of protective measures was fully established, and that it was desirable at once to put an end to them as involving a useless expenditure of public money. Before however, finally condemning the system, it was resolved, early in 1885, to view the effect of the measures in operation in the light of an experiment to be made by closing selected lock hospitals throughout India during one year, and comparing the prevalence of venereal disease among the troops quartered at these cantonments with that existing in them before the experiment and with the venereal prevalence exhibited in stations still protected."

Unless the result of the experiment tried in 1885 proved, beyond question, that mitigation of disease corresponded in some recognisable way with "protection," the experiment could in no way tell against the experience of the preceding 15 years, which shewed progressively higher admission rates under the operation of the Acts.

Two preliminary remarks, have to be made at this stage about two suggestive differences, not merely of opinion, but in methods of judgment, between the advocates and opponents of the Acts. The first is that, as Dr. BARCLAY professed to desire to draw his inferences from a "wider basis" than that which had been previously employed, he ought, instead of selecting the figures of particular stations, while carrying out his experiment in chosen stations, to have submitted the figures obtained from every station, during the period of his experiment, without exception

so that the comparison to be made should rest upon the widest possible basis available. This was the more necessary, for purposes of scientific accuracy, not to say fidelity, because, while even the figures of the selected stations were not favorable to the theories which Dr. BARCLAY tried to extort from them, the figures of the entire field covered by the Acts during the same period, which have been obtained independently of Dr. BARCLAY, are not merely less favourable, but absolutely fatal, to his theories. The second remark is that Dr. BARCLAY, instead of proceeding to examine his statistics with an open mind, undertook their examination with a bias which made the discovery of the truth by him, if he desired to discover it, impossible. As this is a strong statement, its proof had better be given here in his own words. When confronted with increases of disease in protected stations, instead of at once recognising in them arguments, so far as they went, against the efficiency of the Acts, he made up his mind, firstly, that the protective system could not be at fault, and then set about discovering or inventing other causes to explain the facts that thwarted him. "It was quite evident," he says, with either astounding *nuivete* or astounding effrontery, that "some new cause or causes had come into operation to account for these progressive ratios; for, even assuming that the means taken to repress these diseases were entirely powerless, it could scarcely be contended that they actually fostered disease." The only escape from a charge of wilful unfairness, when making such a statement as this, lies in pleading guilty to entire ignorance of the very elements of the controversy on the subject—a controversy of nearly twenty years' standing, with an elaborate literature of its own; for, if there is one point on which the opponents of the Act have always and everywhere insisted (and as regards which they are now borne out by the final verdict of the British Army Sanitary Commission), it is that the enforcement of the Acts has not only not suppressed, but has uniformly aggravated disease. And this opinion, apart from being generally based on experience, was supported by the particular facts that (1) in many examined cases, certification of cleanliness has proved no protection whatever, although, to speak plainly, (2) it has attracted customers and so increased vice, while at the same time (3) men have been known to contract disease, apparently from one another, by resorting in quick succession to certified women in whom disease could not be traced; and finally (4) the concentration of vice among limited female victims of the system has not only destroyed them faster, but in so doing has increased the number of male sufferers from them. Now these differences of opinion, whether sound or unsound, claim a scientific basis in ascertained facts, which have been and can be substantiated; and the audacity or dullness which ignores them, and impudently assumes, without any attempted disproof of them, that the Acts cannot be said to increase disease, should be clearly realised by all honest students of all further statements and conclusions from the same source. Even if unconscious, such manipulation must prove misleading.

The following figures are taken from para. 9 and 10 of Dr. BARCLAY's note:—

Where the Acts were suspended.

| Stations. | Admission Rates. | |
|-------------|------------------|-------|
| | 1875-1884. | 1885. |
| Chuckrata | 164.7 | 129.0 |
| Murree | 124.8 | 184.7 |
| Kussowlee | 116.1 | 343.2 |
| Meerut | 271.5 | 511.9 |
| Allahabad | 315.7 | 527.6 |
| Rawalpindi | 200.1 | 482.2 |
| Meeran Meer | 230.3 | 382.7 |
| Peshawar | 185.8 | 373.5 |
| Delhi | 206.3 | 246.2 |
| Cawnpore | 287.8 | 329.1 |

Where the Acts continue to be fully enforced.

| | | |
|--------------|-------|-------|
| Dum-Dum | 253.0 | 351.9 |
| Barrackpore | 293.9 | 248.8 |
| Dinapore | 267.8 | 311.6 |
| Agra | 307.6 | 434.1 |
| Bareilly | 267.3 | 471.0 |
| Benares | 466.1 | 527.0 |
| Roorkee | 205.9 | 351.5 |
| Muttra | 260.4 | 188.0 |
| Jhansi Lucka | 187.0 | 243.7 |
| Lucknow | 317.8 | 381.8 |
| Faizabad | 278.3 | 317.0 |
| Seetapore | 310.2 | 318.6 |
| Jullundur | 251.2 | 226.0 |
| Umballa | 212.9 | 328.4 |
| Sialkote | 300.2 | 324.9 |
| Ferozepore | 180.2 | 208.7 |
| Mooltan | 239.0 | 250.6 |
| Nowshera | 180.2 | 404.0 |
| Saugor | 272.9 | 220.4 |
| Jubbulpore | 341.8 | 473.2 |

It will be seen from these figures that, with the single exception of Chuckrata, among the ten unprotected stations, and with the four exceptions of Barrackpore, Muttra, Jullundur, and Saugor, among the 20 protected stations, there was an increase in the admission rate per thousand in all other stations. One striking fact is that the decrease shown in the unprotected station of Chuckrata is better than any decrease shown in any protected station, a fact of some importance and significance in relation to the complementary fact, which may be mentioned here in passing, that, in the year of this experiment, 1885, the very worst increase in disease in any station in India was shown in the protected station of Wellington in the Madras presidency. If this system of protection had any scientific consistency, and bore any analogy to the system of vaccination, it would be as though small-pox had broken out most virulently in some place where vaccination had been thoroughly carried out, and had broken out most mildly in a place where there had been no vaccination at all. Not to make too much, however, of this curious double fact, it will be seen that, in the great majority of stations, protected and unprotected alike, the admission rate of 1885 showed an increase over the average admission rate of the preceding ten years from 1875 to 1884 inclusive. What Dr. BARCLAY strangely extorted from this verdict of facts against his system was the curiously unscientific assumption that because, on the whole, larger increases were recorded in the unprotected than in the protected stations, therefore the increase in the unprotected stations must be owing to the want of protection; whereas the increase in the protected stations

must be owing to some other causes! Some scientific consistency might perhaps have been put into this assumption, if the efficiency of protection had been placed beyond question by all past experience—as it has been, for instance, in the case of vaccination; but seeing that, as DR. BARCLAY admits, past experience had been so unsatisfactory as to have aroused doubts of the efficacy of the system up to 1884, and a year's grace had been allowed for a testing experiment in 1885, it would be difficult to match the impudence of the assumption. Even if plausible reasons could be given for the recorded increases in protected stations, it would be necessary to show that these reasons were not also responsible for increases in unprotected stations. But before examining these reasons, it is well to glance at the following figures obtained from official sources independently of DR. BARCLAY, and most unjustifiably suppressed by him in his memorandum:—

Bengal.

| Stations. | 1884. | 1885. |
|--------------------|--------|----------|
| 1. Barrackpore ... | 146.2 | 194.17+ |
| 2. Darjeeling ... | 170.12 | 186.91+ |
| 3. Dum-Dum ... | 264.3 | 345.94+ |
| 4. Dinapore ... | 265.21 | 219.80 - |

North-Western Provinces and Oudh.

| | | |
|-----------------------|-------|--------|
| 5. Agra ... | 284.0 | 434.9+ |
| 6. Bareilly ... | 235.0 | 484.8+ |
| 7. Benares ... | 309.0 | 365.8+ |
| 8. Fategarh ... | 315.0 | 360.2+ |
| 9. Faizabad ... | 192.3 | 229.3+ |
| 10. Jhansi ... | 136.2 | 169.9+ |
| 11. Lucknow ... | 240.6 | 296.8+ |
| 12. Moradabad ... | 403.6 | 971.8+ |
| 13. Muttra ... | 295.8 | 161.7- |
| 14. Naini Tal ... | 273.2 | 304.1+ |
| 15. Ranikhet ... | 262.8 | 241.8- |
| 16. Roorkee ... | 217.6 | 345.4+ |
| 17. Shahjahanpore ... | 284.0 | 326.3+ |
| 18. Seetapore ... | 228.6 | 220.5- |

Punjab.

| | | |
|--------------------|--------|----------|
| 19. Attock ... | 277.22 | 136.69 - |
| 20. Dugshai ... | 211.83 | 278.26+ |
| 21. Dalhousie ... | 212.21 | 72.37 - |
| 22. Ferozepore ... | 154.64 | 153.85 - |
| 23. Jullundur ... | 319.49 | 289.41 - |
| 24. Multan ... | 279.80 | 255.67 - |
| 25. Nowshera ... | 144.34 | 299.81+ |
| 26. Umballa ... | 200.78 | 425.83+ |
| 27. Sabathoo ... | | 244.51 |
| 28. Sialkote ... | 290.22 | 267.59 - |

Central Provinces.

| | | |
|----------------------------|--------|----------|
| 29. Jubbulpore ... | 405.4 | 432.79+ |
| 30. Kanti ... | 179.4 | 264.46+ |
| 31. Pachinari ... | 235.77 | 149.12 - |
| 32. Saugor ... | 184.4 | 126.63 - |
| 33. Hyderabad—Secunderabad | 242.45 | 244.12+ |
| 34. British Burmah ... | 176.86 | 198.8+ |

These figures^o show that, of a total of 34 hospitals given in this return, if we leave out Sabathoo, which affords no material for comparison, we have 33 hospitals,

in only 12 of which disease decreased in 1885, while in 22 of them disease increased. Not only so, but if the figures are scrutinised, it will be seen that, excepting Dalhousie, where the improvement in 1885 was very marked, in the majority of the other 11 stations the improvement was trivial, whereas in many of the 21 hospitals in which disease grew worse, the decline was of a serious character. Now 1885 was the year of special experiment, in which protective arrangements were being specially tried; and if the protective system were judged by the result of 1885 alone, they would have, in sheer honesty, to be confessed a complete failure. If, up to 1884, grave doubts existed of the utility of the system, and the results of 1885 declared it an utter failure, with what honesty, (not to speak of scientific precision,) can intermediate averages be cooked up in 1886 to secure any other verdict?

Of what use is a special experiment in a particular year if, when the system on trial is proved a disastrous failure, we refuse to accept the evidence, in the sense in which it has been uniformly interpreted, and fly back on the manipulated averages of an anterior period—which has been acknowledged to tell against the system—in order to extort proofs in favor of a foregone conclusion? Whatever excuse may have been manufactured for confining the comparison to the stations in which the system had been tried for an equal number of years, it is impossible to justify the suppression of the figures just quoted. If the value of any medicine were being tested, and its use in ten stations, in which it had been tried for ten years, was carefully examined, but it was found that in twenty stations, in which it was used in the year before the enquiry, it was found to be deadly in its effects, it would surely be equally ridiculous and dishonest to exclude all consideration of these deadly effects, merely because, in 10 of these 20 stations, the medicine had been used for longer or shorter periods than in the other 10.

With these facts before him, the intelligent statistician will hardly demand any special examination of the methods in which DR. BARCLAY has tried to explain away the unquestioned increase of disease in protected stations. He attributes it to three main causes: (1) the youth of the soldiers under the Cardwell Scheme, (2) the unmarried condition of the majority, and (3) movement of troops, which is said to increase disease. The objections to the first two explanations are that the years of the greatest accession of young men do not correspond with the years of the greatest prevalence of disease, and that until the actual disposition of the married strength is accurately recorded—which no attempt is made to do—it is impossible to study it as a factor in the etiology of disease. As regards the third explanation, not only does it fail to explain increases in stations entirely off the line of large troop movements in particular years, but no attempt is made honestly to trace its effects in unprotected stations. If troop movements actually increase disease, why should they not do so in unprotected as well as in protected stations? In fact, it is loosely assumed, as already shown, that protection must effect disease, and the want of it increase it; and the position really taken up throughout is that, inasmuch as there must

^o Taken from Twelfth Report of working of Lock Hospitals in North-Western Provinces and Oudh, 1885: Annual Report of Punjab Lock Hospitals, 1885: Review by Chief Commissioner of Report on Lock Hospitals Central Provinces, 1885: Annual Report of Working of Secunderabad Lock Hospitals, 1885: Report on Lock Hospitals, British Burmah, 1885: Annual Reports on Bengal Lock Hospitals, 1885, with Government Resolution thereon.

infection of disease in all stations, it can only be owing to the want of protection in unprotected stations, but must be owing to some other causes in properly protected places! Everything comes to the statistician who expects; and it is not perhaps surprising that to the mind brought by Dr. BARCLAY to the figures examined above, the figures echoed the astonishing conclusions which they did.

The foregoing figures relate to the Bengal Command, and have been selected from Dr. BARCLAY's figures, not because the Madras and Bombay figures, with which it is unnecessary to burden this production, differ in any characteristic feature from those of Bengal, but because other figures for testing their value by comparison have not been so easily procurable by the writer as figures from Bengal. But the following figures taken from Dr. BARCLAY's own note, and relating to all India, will shew at a glance the general and steady growth of disease prevalence between 1871 and 1885, inclusive, 15 years during which the Acts were enforced throughout India:—

| | | |
|--------------|--------------|--------------|
| 1871...196.8 | 1876...189.9 | 1881...260.5 |
| 1872...179.0 | 1877...208.5 | 1882...265.2 |
| 1873...166.7 | 1878...271.3 | 1883...270.3 |
| 1874...192.7 | 1879...234.8 | 1884...293.9 |
| 1875...205.1 | 1880...249.7 | 1885...342.7 |

The Acts having been enforced in all cantonments from 1871 to 1880, and suspended in a few stations between 1881 and 1884, irrespectively of the special experiment tried in 1885, it appears that though, in spite of occasional fluctuations, there was a general tendency to increase during the incidence of the Acts, yet there seems to have been a much more rapid growth from 1871 to 1878, when the Acts were enforced everywhere, than during the four years from 1881 to 1884, when the Acts were withdrawn from some localities. Even the large figure 293.9 in 1884 does not shew such a big jump from the figures of any of the three preceding years as that disclosed between 1871 and 1877, or even between 1877 and 1878. Whatever the cause of this state of things, the fact is undeniable that disease increased at a much worse rate during the general enforcement of the Acts than during their partial suspension: while, so far as Dr. BARCLAY's review was concerned, the very worst results were secured in 1885, the year of the special experiment, when it may be reasonably assumed that the advocates of the Acts, who were in charge of the measures taken under it, were doing their best to obtain satisfactory results under it. It has been said indeed, that anything can be made of statistics. But it is only fair to remember that the statistics here utilised have been furnished by the supporters of the Acts and endorsed by the Indian Medical Department as affording a conclusive mathematical demonstration of their success.

III. It remains only to consider the period following the abolition of the Acts. Of this period the years 1889, 1892, and 1893 are here taken up only, because the figures relating to them have been considered bad, have been published with some amount of outcry, and have formed the subject of special recommendations made by the Indian medical authorities to the British Army Sanitary Commission. Some reference has been made in the

opening remarks of this paper to the verdict of the British Army Sanitary Commission upon some of them. It may be added that the figures were considered so different from those of earlier years that the British Army Sanitary Commission "could not help enquiring whether they have been prepared throughout on the same system, or some changes have been introduced which may account for at least part of the increase." (1) No answer has been published to this enquiry; and the fact is significant in view of the suspicion that changes have been made, if not as some professional witnesses have publicly stated by the inclusion of diseases not strictly of a venereal character, though aggravated by venereal complications, at any rate by reckoning every re-admission of the same man as a new diseased man. Immorality belongs to individual identities, and if a man is admitted 3 or 5 times a year to hospital for this disease, he still remains one and the same individual, and the 30th part of a corps of 500 men; and it is monstrous to reckon him as 3 or 5 different men, for the dishonest purpose of representing 30th or 50th, i.e. 10th part of the corps, as being disabled from disease all the year. At any rate, we have seen what view the highest medical Military authorities in Britain have taken of the figures of 1889.

Of those for 1892, we find the British Army Sanitary Commission saying, in page 160 of their report, just published:—

"For the last five years the general venereal ratios for the European army of India stand thus° per 1,000 of strength. The ° 1888 ... 370.6 ratio for 1892 shews an increase of 1889 ... 418.5 9 cases for 1,000 over 1891, but the 1890 ... 503.5 rate for 1891, it will be observed, was 1891 ... 400.7 over 100 per 1,000 less than it was in 1892 ... 409.9 1890. Still, even with this diminution

as compared with 1890, it admits of no question that in 1892 venereal disease prevailed among European soldiers in India to such an extent as to constitute a most serious cause of inefficiency. In a separate memorandum, which we submitted in December 1893, we discussed this question at length, and gave the reasons why we arrived at the conclusion that the evil had been very slightly mitigated in India under the Lock Hospital system, and that the re-introduction of the system on sanitary grounds could not be recommended."

Apart from the double verdict, pronounced on the system in 1891 and repeated in 1892, we observe the same fluctuations in admissions which have characterised the returns of earlier years. The reader will remember that in 1890, when the Acts were supposed to have been abolished, they were being secretly carried out in several Indian cantonments; so that Lord ROBERTS, who contradicted this discovery when it was first made, subsequently apologised for his denials and admitted its accuracy. The increase of disease in these years, when the Acts were being secretly enforced, rather bears out the contention of their opponents that they have always promoted disease.

Of the figures for 1893 the only detailed account yet before the public will be found in the "Army Medical Department Report for the year 1893, Vol. XXXV," lately published in London, from pages 109, 136, and 142

at which, *namely*, respectively to Bengal, Madras and Bombay, the following figures have been taken:—

| | Admissions. | Rates per mille. | Constantly sick. | Ratio. |
|--------|-------------|------------------|------------------|----------|
| Bengal | 19,348 | 449.9 | 1598.99 | 36.77 |
| Madras | 6,447 | 488.0 | ... | 42.76 |
| Bombay | 6,268 | 463.8 | ... | 33.63 |
| Total | 32,058 | 3)1890.7 | ... | 3)113.16 |
| | | 465.5 | ... | 87.72 |

It will be seen that the total admissions in all India aggregated 32,058, giving an average admission rate per thousand of 465.5, with a "constantly sick" average of 1598.99 for Bengal, and a total ratio of "constantly sick" for all India, of 87.72. It is to be regretted that the total "constantly sick" for all India, while indicated in a manner by the ratios per thousand given for Madras and Bombay, are not plainly stated in figures as for Bengal. However, the ratios of "constantly sick" given for Bombay and Madras, when considered in relation to the total admissions for the three presidencies given in the first column, which shows that the whole admissions for Madras and Bombay were about two-thirds of the total admissions for Bengal, enable us to estimate that the "constantly sick" in Bombay and Madras, if not less than 1,062, would not be more than 1,593; giving a rough, freely estimated total of 3,000. With these figures before us, it must have surprised all informed students of the subject to find the Hon'ble Sir G. WHITE, Commander-in-Chief in India, making the following strange statement in the Legislative Council of India on the 7th February last:—

"The extent to which disease prevails in the Army, and the probability that the removal of restrictions that could formerly be enforced would increase the extent of this disease, and the consequent inefficiency of the Army, have been exhaustively put before Her Majesty's Government. How necessary such a representation is, may be inferred from the fact, now notorious, that in the year 1893 the admissions to hospital for disease alone among our British soldiers in India were 466 per thousand. This is practically 50 per cent. of strength. For a rough and ready calculation this proportion may be adopted, and it gives us, out of a total of 70,000 British soldiers, 35,000 admissions to hospital for diseases every year."

The gravest objection to this unfortunate misrepresentation, of which His Excellency has doubtless been made the unconscious mouthpiece by military-medical advisers, is not that the ratio of admission has been overstated by a fraction, and the total admissions overdrawn by about 3,000 men when the actual figures, as shewn above, were available, and would be preferable, but that the Commander-in-Chief has unaccountably overlooked the real meaning of the Hon'ble LEE WARNER's question "whether the statistics of admission included re-admission of the same diseased patient, which are counted fresh admissions," and His Excellency's answer, "Yes." As a matter of fact, not only is it unjustifiable to reckon actual admissions at 35,000 when only 32,058 are exactly known to have occurred, but it is surely inexcusable to reckon every admission as a man, when it is known that certain men, whatever their number, were admitted

more than once; *namely*, according to the statement, men go in and out of hospital several times, for long periods, sometimes at least remaining for a few days, if sometimes longer; even the very doubtful statement of which no proof is given, that 30 days form a fair average of the length of treatment for all kinds of venereal disease, would not affect the undeniable fact that the daily average of men in hospital is the only correct test of the number of men incapable of taking the field. The return of "constantly sick" therefore affords a more accurate estimate of the inefficiency of any fighting force than the total admissions during a whole year. To count a man who may be in hospital five times a year as five diseased men, when, of a band of 20, he may be the only diseased one against 19 healthy men, and to reckon him as one-twentieth of 100 fighting men, when he is only the one-hundredth, is surely a trick which the head of the army, if he had been carefully informed, could never have encouraged, and indeed may be depended on now that it has been discovered, to visit with his displeasure. Taking the total of the admissions at even 35,000, the figure given by Sir G. WHITE and the "constantly sick" at from 3,000 to 3,500, which His Excellency will find a large allowance, it is seen at a glance what a number of re-admissions of the same persons must have taken place. Taking the total British Army at 70,000 and the "constantly sick" at even the large figure of 3,500, we find the inefficiency caused by venereal disease to amount at the outside to one-twentieth of the entire force, which is a very different figure to the one-half, or 50 per cent., to which His Excellency's medical advisers have committed him.

One consequence of blindly floating down arguments on figures furnished by incompetent advisers is seen in the following painful statement made by the Commander-in-Chief, which involves a grave wrong to all the married soldiers, and all unmarried men of good character and blameless life, in the Army:—

"The same figures show that in two years the whole British Army in India will have been treated in hospital for disease. The inefficiency that this wholesale infection must bring about under the hardships and exposure of a campaign, I cannot reduce to figures, but at the same time I cannot contemplate it without the gravest apprehension."

Is it seriously believed by any sane surgeon in the British Army in India that in the course of two years every British soldier will have been incapacitated for war service by venereal disease? If not, who is responsible for putting this mis-statement into the mouth of the Head of the Army, and getting the insult authoritatively published? If the picture which His Excellency has tried, at the suggestion of untrustworthy advisers, to impress on the public imagination were true—if, in two years, every soldier became infected, and if many men or any men, were admitted more than once, and the present inaccurate method of reckoning every admission of the same man as another man were continued—as why should it not, if it is adopted now?—we should be confronted with the *reductio ad absurdum* of the mental processes of the Indian Medical Department in a return of men rendered inefficient by disease, whose number exceeded the entire recorded strength of the British Army!

DISINFECTANTS: THEIR ACTION AND USES.

By **ROBERT G. S. OSWALD, M.D., C.M., M.S.C.**

CHAPTER XIII.

GERMICIDAL DISINFECTANTS THAT REQUIRE COMPETENT SCIENTIFIC APPLICATION: BROMINE, CHLORINE, EUCHLORINE, AND IODINE—THEIR CHARACTERS AND ACTIONS.

BROMINE.

(467). BROMINE = $\text{Br} = 80$, is a powerful aerial disinfectant having properties much in common with iodine, but it should not be disengaged in large quantities, and great care should be taken to prevent excessive evolution, as its vapour is highly irritating to the eyes and lungs.

CHLORINE.

(468). CHLORINE = $\text{Cl} = 35.5$, does not occur free in nature though in combination with sodium it is found native in large quantities in the form of salt (NaCl). It is under ordinary conditions a bright greenish-yellow gas, (specific gravity 2.44), with a highly corrosive action and an asphyxiating insupportable odour, but under a pressure of five atmospheres it may be condensed into a yellowish liquid (sp. grav. 1.33) which no amount of cold can reduce to the solid state. Chlorine, however, freely dissolves in about one-third of its volume of water, and if this solution be subjected to sufficient cold (0°C) it will deposit crystals which have the formula $\text{Cl}_2 \cdot [10(\text{H}_2\text{O})]$. Under the influence of light it combines directly with hydrogen, but such combination cannot take place in the dark unless the chlorine had been *insolated*, i.e., first exposed to sunlight for some time.

(469). It also combines *directly* with most of the metals, and more particularly with mercury, over which it cannot, therefore like other gases, be collected.

(470). In presence of water it acts as an energetic oxidiser, appropriating hydrogen and liberating oxygen which (latter), while in the nascent state, has very great affinities for all substances whose oxygen-combined molecule is unsaturated. Thus *sulphurous* acid is rapidly formed by chlorine into *sulphuric* acid. $[\text{H}_2\text{SO}_3 + \text{Cl}_2 + \text{H}_2\text{O} = \text{H}_2\text{SO}_4 + \text{O} + \text{Cl}_2 + \text{H}_2 = \text{H}_2\text{SO}_4 + 2(\text{HCl})]$

(471). Chlorine may be prepared (a) by heating hydrochloric acid with binocide of manganese $[\text{MnO}_2 + 4(\text{HCl}) + \text{Aq} = \text{MnCl}_2 + 2(\text{H}_2\text{O}) + \text{Aq} + \text{Cl}_2]$; (b) By acting with sulphuric acid on a mixture of common salt and manganese dioxide: $[\text{MnO}_2 + 2(\text{NaCl}) + 2(\text{H}_2\text{SO}_4) = \text{MnSO}_4 + \text{Na}_2\text{SO}_4 + 2(\text{H}_2\text{O}) + \text{Cl}_2]$; (c) By exposing chloride of lime to the action of dilute sulphuric acid $[(\text{CaOCl}_2) + 2(\text{H}_2\text{SO}_4) = 2(\text{CaSO}_4) + 2(\text{H}_2\text{O}) + \text{Cl}_2]$

(472). It discharges vegetable colors, bleaches organic pigments, purifies the air, destroying mal-odours, and noxious effluvia $[2\text{SH}_2 + \text{Cl}_2 = 2(\text{HCl}) + \text{S}]$, and misamata as also modifies organic matters (rendering them more or less innocuous) by one or more of three ways:—

(a) By appropriating for itself and then abstracting the hydrogen which these bodies contain. Thus:—alcohol is converted into aldehyd and hydrochloric acid is formed $[\text{C}_2\text{H}_5\text{O} + \text{Cl}_2 = \text{C}_2\text{H}_5\text{O} + 2(\text{HCl})]$, while a portion of the carbon is deposited.

(b) By substituting itself for some of the hydrogen and combining with the hydrogen displaced $[\text{C}_2\text{H}_5 + \text{Cl}_2 = \text{C}_2\text{H}_4\text{Cl} + \text{HCl}]$.

(c) By indirect oxidation where, in the presence of water, the chlorine attacks the organic substance, seizing upon a portion of its hydrogen and liberating the oxygen that was in combination with the abstracted hydrogen, and consequently that portion of the organic matter that has been decomposed by the chlorine yields up its oxygen to the other portion, making it deposit a good part of its constituent carbon.

(473). EUCHLORINE, which practically is a mixture of chlorous acid with free chlorine, may be slowly disengaged by throwing small quantities of chlorate of potash into an open vessel containing fuming hydrochloric acid. It has a similar effect on organic matters as has chlorine than which it is less unpleasant to smell. A similar decomposition may take place by electrolyzing sea-water on which is based the Hermit system of disinfection that has given such grand results in the experiments lately tried at Worthing and Havre.

IODINE.

(474). IODINE $\text{I} = 127$. Though found in large quantities combined with sodium in *Kelp*, Iodine does not occur free in nature. To obtain it the kelp is carefully dried and slowly burned and then extracted with water: The contained chlorate of potash (KClO_3), hyposulphite of sodium ($\text{Na}_2\text{S}_2\text{O}_4$) and sodium sulphide (Na_2S) are removed by crystallising out and the mother liquor is then distilled (at a temperature not exceeding 212°F) with sulphuric acid and binocide of manganese $[2(\text{NaI}) + \text{MnO}_2 + 2(\text{H}_2\text{SO}_4) = \text{Na}_2\text{SO}_4 + \text{MnSO}_4 + 2(\text{H}_2\text{O}) + \text{I}_2]$ and the purple vapours (sp. grav. = 8.716) of Iodine are condensed as dark-grey scales (sp. grav. = 4.95) of a metallic lustre, much resembling black lead and melting at 170°F .

(475). On contact with sulphuretted hydrogen in the presence of water, iodine precipitates the sulphur while it combines with the liberated hydrogen to form hydriodic acid in solution $[\text{I}_2 + (\text{SH}_2 + \text{Aq}) = \text{S} + 2(\text{HI} + \text{Aq})]$ but the oxygen of the air again decomposes this solution $[2(\text{HI}) + \text{O} = \text{H}_2\text{O} + \text{I}_2]$ and combining with the hydrogen to form water liberates the iodine which forthwith dissolves in the water to which it imparts a reddish color.

(476). When iodine acts upon ammonia it does not liberate the nitrogen but simply removes two-thirds of the hydrogen, in whose place it substitutes itself $[\text{NH}_3 + \text{I}_2 = \text{NHI}_2 + 2(\text{HI})]$ while at the same time other portions of the Iodine combine with the liberated hydrogen to form hydriodic acid.

(477). It has a stronger affinity for oxygen than has bromine or chlorine and nitric acid (HNO_3) which has little or no influence on those gases, readily oxidises it into Iodic acid $[\text{I}_2 + 10(\text{HNO}_3) = 6(\text{HIO}_3) + 2(\text{H}_2\text{O}) + 10(\text{NO})]$; but its affinity for all the other elements being

weaker; bromine and chlorine easily displace iodine from its non-azotized compounds, whereas, it (iodine) displaces them (bromine and chlorine) from their oxygenised combinations.

(478). Like bromine and chlorine, iodine can act as an oxidiser which may be applied directly to organic molecules; but unless the hydriodic acid be saturated, as it is formed, it does not occasion phenomena of substitution (as does iodine with organic bases) and the products of iodized substitution are generally prepared by indirect methods.

(479). Iodine dissolves freely in alcohol and ether; but very sparingly in water, with the last it forms a light-brown solution which is slowly decomposed and the iodine combines with the hydrogen.

(480). When thrown on a red hot shovel, iodine is rapidly diffused as a powerful deodorant vapor which decomposes sulphuretted hydrogen, arrests putrefaction, and destroys putrid emanations, but its easy condensation and the ugly manner in which it disfigures clothing render it less useful than chlorine than which it is infinitely more difficult to properly diffuse.

(481). Iodine may also conveniently be suspended from the ceiling in gauze-flannel bags, or its saturated aqueous solution may be dispensed as a spray to greatly add to the comfort of the patients and to the sanitary improvements of wards where variola cases are lying or where sloughing or profuse suppuration is going on.

A MIRROR OF PRACTICE.

POST-DIPHTHERITIC PARALYSIS, ILLUSTRATED BY TWO CASES.

By SURGN.-CAPT. PATRICK HEHIR, M.D., F.R.S.E.,
F.R.C.S.E., D.P.H. (Cantab).

Lecturer on Medicine and Pathology, Hyderabad
Medical School.

THE cases of post-diphtheritic paralysis that have been recorded in India, if gauged by the literature extant, are sufficiently few to merit the publication of those coming under the observation of practitioners in various parts of this Empire. It is well known that diphtheria occurs so much more frequently in urban than in rural districts, as to justify our believing it to be a town disease, this statement is even truer of India than it is of England and European countries generally. During a period of 14 years in mofussil India, I have altogether only met with eleven cases of diphtheria, and in only one of these did it occur in a member of the indigenous community—a Mahomedan male child of three years—who recovered after passing through (1) an attack of severe post-diphtheritic aphonia lasting 7 weeks from partial paralysis of the constrictors of the pharynx (3) albuminuria, (4) diabetes insipidus, (5) broncho-pneumonia, lasting two months, during which he suffered seven times from attacks of convulsions under ordinary circumstances. When met with, however, the disease is as characteristic in this country as it is in England, and the sequelae are as frequent and as severe, especially when the disease occurs in the cold weather.

Of the other ten cases, two were in European male adults; seven in Eurasians, (one man, one woman, two boys and three girls); and one in a Mahomedan boy. Of these ten cases, in four we had grave complications—two with diphtheritic paralysis, one with acute croupous pneumonia, one with cardiac syncope, complicated with simple acute endocarditis.

As regards the frequency and destitution of diphtheria, it cannot be alleged that mine is an exceptional experience, for the reason that during the last eight years I have inquired of at least fifty medical men as regards their Indian experience of diphtheria, and the invariable reply is that they have never met with more than a few cases. The conclusion one arrives at is that diphtheria in the mofussil of India must certainly be rare.

In Calcutta, Madras, and Bombay, this disease is only too frequently met with, and the reason for the difference in prevalence in town or city and country places is doubtless the same as gives rise to the same difference in Europe. The extreme rarity of its occurrence amongst the inhabitants of this country, however, is a matter deserving of a moment's reflection, and the interest attaching to it is enhanced by considering the fact that true enteric fever is also a comparatively rare malady amongst them. Both are specific diseases, both attack a part of the digestive tract (principally), and curiously enough the disease in both cases has its chief seat in the mucous membrane and adjacent lymphatic tissue and lymphatic glands. Enteric in the agminate and solitary glands, and diphtheria in the tonsils and other glands, the structure which bears the brunt of both diseases is therefore adenoid or lymphatic tissue; in diphtheria, that of the tonsils and the pharyngeal lymphatic glands, or the continuous membrane of lymphatic tissue which occupies this region.

These are a few stray thoughts, which crossed one's mind, whilst considering the facts connected with the following two cases of post-diphtheritic paralysis, which were followed by localised paralysis.

The first case was that of an Eurasian girl, *et.* 10 years, who was attacked with an acute inflammation of the throat on the evening of the 25th September 1893, but was not seen by me until the morning of the 27th, when the disease was diagnosed as acute tonsillitis supervening on chronically hypertrophied and indurated tonsils. On the morning of the 28th, however, the false membrane with its greyish color and leathery character had appeared, and the urine was found to be loaded with albumen. She now also suffered from aphonia, hurried breathing, a quick full pulse, and a temperature of 102.5°F. Constipation, a thickly furred tongue and a constant dry cough, although the lung sounds were clear and normal. There was nothing peculiar about the case, so far as the early stage was concerned, nor even in the course of the stage, except that she remained unusually long in bed, was intensely weak, and fainted twice from cardiac debility. For a period of 14 days, after all signs of the throat affection had disappeared, she was not even able to sit up in bed. On the 18th day after the fever left, she was propped up with pillows, and in a week was able to sit up for about half an hour at a time. On the 24th day after the subsidence of the pyrexial symptoms, she was permitted to sit

on a comfortable couch, which was placed adjacent to her bed. When she tried to get on to the couch from the bed she found that she was quite unable to stand, but not suspecting her infirmity, fell to the ground. We then inquired carefully as to the state of the various groups of muscles, and found that in several regions there was complete paralysis, whilst in others there was only paresis.

We first examined the eyes and found both pupils markedly and permanently dilated, whilst she was unable to distinguish any one member of her family, although she could recognise her mother and two (out of four) of her aunts when they stood at the door six yards off, but they always appeared double. She could not read even large print, and found any light very disagreeable. Consequently she could not tolerate an ophthalmoscopic examination. At rest there was an inward squint in both eyes, but after a week this became very much more marked in the left. The axes of both eyes were displaced inwards and downwards. This state lasted for 9½ months and left her permanently myopic.

Next we found her hearing very defective. At first we put this down to the quinine she was taking (9 grains a day); because of ague which she had suffered from for 8 months, and an enlarged spleen, which reached the crest of the ilium below and the inner border of the right rectus abdominis, and upwards to the 7th rib. Stopping the quinine however, did not remove the deafness, which gradually disappeared *per se*, and by the end of the 8th week left her completely.

The aphonia was of a peculiar kind. We could sometimes hear her; but, as a rule, could not distinguish what she said.

We next found that the erector spinae were very weak on both sides but not paralysed, whilst the whole of the external rotators of the thigh and the muscles of the anterior tibial region were paralysed on both sides, but especially on the right. The pectorales major and minor, and the serrator magnus appeared also to be weak. The last-named condition caused great dyspnoea. The deltoid muscles and the triceps supplied by the posterior interosseous nerve were paralysed.

Up to the 11th week after the paralytic symptoms began, her condition was one of interrupted retrogression presenting the appearance of a patient who was in the last stage of general complication with bulbar paralysis. She could neither speak nor make her wants known, as she had previously done, by signs or in writing. There was difficulty of swallowing, especially of solids, and even liquids could only be drunk in small quantities at a time. When more than a dessertspoonful, say about an ounce, was drunk, she would suffer the greatest possible distress in which dyspnoea predominated; part of the fluid would enter the larynx, and set up violent coughing, part of it would return through the nose and give rise to great pain and violent sneezing; the face would become blue in color, the pulse thready, and the first sound at the apex of the heart inaudible. She now passed her motions involuntarily, and there was incontinence of urine—in short, she appeared to be a helpless cripple, hopelessly paralysed. Together with the paralysed state of the muscles, they had diminished in size, and lost all their reaction to galvanic and faradic electricity.

Yet curiously enough, when during eating or drinking, these terribly distressing symptoms had attained their maximum of severity, and the patient appeared to be, on the point of asphyxiating, she would suddenly appear to be relieved and in two minutes would be ready for another potation, and indeed would shew signs of great eagerness to be supplied with more, as the longer she went on drinking, the less became the distress. This would occur once or twice only during a meal. When she had become so bad that we thought it impossible for life to continue in that condition, she began to rally in a most surprising way. The first groups of muscles to recover were those of articulation and deglutition. This was very fortunate; for it enabled her to express her wants and swallow her food, which obviated the disgusting process of rectal feeding, which we had carried on for four weeks. Next the muscles of her legs and trunk began to recover, and lastly those of her arms.

The abnormal movements of the eyes continued for 5½ months, whilst the dilatation of the pupils, together with indistinct vision, remained for nearly ten months. This was a specially distressing symptom in a girl who was very studious. We got her a pair of spectacles, + 4 Dph., yet they assisted her but little. By accident one day, she took up her father's glasses and placed them over her eyes and found that she could read the smallest print with the combined lenses. Her father's lenses were + 2.5 Dph.—the problem was solved. We got her a pair of spectacle lenses of + 6.5 Dspherical, to go about and to read. Here again our aid came rather late, for a fortnight after using the lenses, vision began to return, and from being hypermetropic, she became myopic to the extent of 1.5 Dph., and has remained so.

It is now 1½ years since the girl suffered from diphtheria, and it may be said that since that time she has never had one day's good health. She is always ailing one way or another—chiefly, however, with dyspeptic symptoms and palpitation.

The second case lacks much of the interest attaching to the first, but it has its interesting points also, especially those connected with the eye. Anthony C., *et.* 12 years, Eurasian, who had previously been in good health, but was thought by the parents to be getting thin for some months before the attack. Three weeks after a mild attack of diphtheria, which began on the 13th June 1891, and ended on the 19th, he suffered from double vision, and a high-pitched tone of the voice, whilst the legs would suddenly give way when walking, causing him to be precipitated to the ground. The symptoms progressed till he could only see with the left eye, the pupil of which was normal. Eventually complete dilatation and paralysis of accommodation set in. Four weeks from the day of the attack he had almost complete paraplegia, with all its usual symptoms.

At the end of the third month he had recovered his vision and voice, but had still to use crutches. These he left off about the eleventh month, and he is now, four years after his disease, a smart and active boy.

Both cases were treated in the same way: by strychnine, galvanic electricity, massage, rectal feeding, stimulants, iron, quinine and cod liver oil. As the fact of the paralytic symptoms is the main reason for this contribution, we have confined our remarks specially to it.

FOUR CASES OF PORRO'S OPERATION AT THE LADY KINNAIRD MEMORIAL HOSPITAL, LUCKNOW.

By LILLIAN JENKINS, L.B.C.P. & S., Edin.

Physician in Charge.

CASE I.—Lutchmin, Hindu, purdah woman, age about 26.
Previous history.—First child born in 1885 with difficulty. Fine, healthy child. Still living.

Three years afterwards, second child was delivered by high forceps. There was at the time evident contraction of the pelvis, but of no high degree. After this, *osteomalachia* advanced rapidly. A year after her second confinement, the patient presented herself at the K. M. Hospital. She was walking with her back bent to almost a right angle. The internal conjugate diameter of the pelvis barely admitted two fingers. The disease seemed, for the time being, quiescent.

The patient attended the dispensary for attacks of pain in her thighs and back at intervals from this time on. In 1890 abortion was induced at an early period, but when in 1891 the patient again became pregnant, a repetition of this treatment was refused, and on 6th February 1892, Porro's operation was performed.

The operation presented no special features, beyond the accidental tearing of the right broad ligament, from which there was profuse venous bleeding. The tear had to be secured by stitches which afterwards sloughed out and retarded convalescence.

The pedicle was secured by an elastic ligature and transfixed by knitting needles and drawn down to the lower angle of the wound. The wound was closed by silk sutures, and the whole dressed with iodoform and salicylic wool.

The patient recovered perfectly within a month, and her child thrived well.

CASE II.—Jaldu, Hindu, aged 27.

Previous history.—First child born three years ago without difficulty, very fine looking boy, after her confinement patient suffered from pains in her thighs, debility and general 'malaise' ('garni'). The pains got better in time, but her difficulty of walking increased.

Present condition.—Very small, slightly made woman. Pelvis slightly contracted. Internal conjugate barely admits one finger. Os fully dilated. Membranes ruptured. Said to have been in labor three days. No attempts at fixation of foetal head. Pulse 124. Temperature 102.4°F. Signs of great exhaustion. Patient's friends consented to radical operation, and she was at once anaesthetised.

Incision made in median line about 8 in long. Peritoneum divided on director. Uterine wall presented and was divided by scalpel and transverse tearing. Child extracted by the feet with some difficulty. Showed signs of asphyxia but quickly recovered. Uterus then drawn out of wound and placenta removed. An elastic ligature was then passed round the cervix and secured. The uterus and appendages were removed by cutting through the cervical tissue $\frac{1}{2}$ inch above this ligature. The stump was now further secured by a stout ligature and transfixed by knitting needles at the lower angle of the wound. It was carefully dried and the peritoneum sewn over it. The wound was closed by (1) continuous peritoneal suture; (2) interrupted suture through muscular walls and skin.

Dressings. Iodoform, protective, mercury wool, and many-tailed bandage.

Progress of Case.—Patient made an uninterrupted recovery. Temperature never rose to 100°F. after the operation. Pedicle separated at the end of a fortnight and convalescence was complete in three weeks.

CASE III.—Rukmin, Native Christian, age 25, primipara. Case of extreme pelvic deformity, dating from early childhood and due to acute rickets in all probability. Patient walks with her spine bent at a right angle, and in standing or walking, aids herself by placing the hands upon her knees.

Internal conjugate diameter of pelvis admits two fingers with difficulty. Married 25th March 1894. No subsequent menstruation.

On 27th December 1894, admitted into hospital with labor pains. Os partially dilated, membranes intact. Operation performed under CHCl₃. The mechanical difficulty of the operation was considerable owing to the extreme deformity, otherwise it presented no special features of interest. The child showed signs of vitality immediately on removal. Steps of operation as in previous cases.

Progress of case. Was uninterruptedly satisfactory. Dressing changed every 2nd or 3rd day; abdominal wound healed by first intention. Stumps separated 15th day. There was a small fistula communicating with the cervical canal on separation of the stumps, which gave no trouble and closed before patient was ready to sit up. Convalescence established at end of 21 days. Patient discharged with her child, a week later.

CASE IV.—Parbati, aged 35, Hindu.

Previous history.—Married 22 years, no trouble with her early confinements, of which there were several. Does not give any history of illness resembling osteomalachia, but describes a very difficult labor which took place five years ago, when the native midwife used great force and the child was born dead.

Patient first admitted into K. M. Hospital at the end of 1892. She was then in labor and considerable pelvic deformity was discovered. Turning was performed with perforation of the after-coming head.

On 28th January 1894 patient was again admitted into hospital. The membranes had ruptured and the small diameter of the head engaged. Craniotomy was performed and the patient made a good recovery. On 25th January 1895 patient was admitted for the third time under similar conditions. The os was fully dilated and the membranes ruptured during the first pain after admission: The patient's friends consented to a radical operation which was at once undertaken.

NB.—The internal conjugate admitted two fingers with difficulty.

Operation.—Incision median line 7½ inches long. Peritoneum slit up on director. Uterine wall incised in line of wound and torn transversely. Child extracted by head. No asphyxia. Placenta removed and uterus drawn out of wound; secured with elastic ligature and transfixed with knitting needles. Pedicle cut off short above these. Peritoneum sewn over stump, which was well dried and dusted with iodoform. Wound closed as in previous cases, and the whole dressed with iodoform and mercury wool.

Progress of case.—Uninterruptedly satisfactory. Temperature never rose above 99°. Stumps separated 15th day. Wound healed by first intention. Patient left the hospital with her child at the end of a month.

**POST-MORTEM NOTES OF A CASE OF
CARDIAC RUPTURE.**

By Asst. Surgeon. J. J. SRINIVASAGAM PILLAY,
B.A., L.R.C.P. & S.E.

Assistant to the District Medical and San'y. Officer, Malabar.

On Saturday, 26th May 1895, at 4 P.M., I examined the body of a fairly nourished Hindu male, aged 35 years, who had come by his death under the following circumstances:—While driving a heavily laden bullock cart, the bullocks suddenly became unruly and dragged him off his seat. He came down heavily on his back, and one of the wheels of the cart passed across his chest from right to left. Death was instantaneous. A *post-mortem* examination was held three hours after death.

External appearances.—Body cold. Rigor mortis just commencing in the extremities. Eyes closed. Blood had flowed from the nose and mouth. The following abrasions and bruises were found on the body:—(1) Slight abrasion behind the left elbow joint. (2) Slight abrasion on the outer aspect of the left knee joint. (3) Abrasions on the posterior and outer aspects of the right elbow joint. (4) Abrasion with ecchymosis about the middle of the back which runs obliquely upwards from right to left. It is well marked towards the right side, where it is about 3 inches broad. (5) Abrasion with ecchymosis running obliquely from the right shoulder joint to about the middle of the left side. It is irregular and broad, extending in front from the sterno-clavicular articulation to the pit of the stomach, and on the left side, from a little below the axilla down to the 9th rib.

Internal appearances.—On opening the thorax the lungs presented a congested appearance from extravasation of blood into their tissues. On gently separating the lungs, the heart was found to be ruptured—the rupture extending on the right from above the entrance of the *superior vena cava* obliquely to the left side, and almost severing the pulmonary artery and aorta at their origin. The *superior vena cava* and the left auricle are also torn. The cavities of the heart are empty. In the left pleural cavity there is about 30 ounces of fluid blood and in the right about 12 ounces.

Lungs.—There are patches of congestion and extravasation in different parts of the lungs—these being most marked towards the bases. There is a lacerated wound in the lower lobe of the right lung posteriorly, which corresponds to a fracture at the angles of the 7th and 8th ribs.

There is no injury to any of the other bones.

Abdomen.—Liver and spleen slightly congested, but healthy; stomach contains partially digested food but is otherwise healthy; kidneys and other organs are normal. Brain rather anæmic. Opinion as to cause of death: *Immediate cause* rupture of the heart.

**THIRTEEN CASES OF HEREDITARY ATAXIA IN A
SINGLE FAMILY.**

NEFF has reported thirteen cases of ataxia in adults in four generations of one family, with a distinct hereditary history. All of the cases were characterised by a marked similarity of the symptoms. In all of the cases but two the onset was observed between the ages of fifty and sixty-five, and of these two the first symptom was noted in the one at the age of sixty-two, and in the other at the age of sixty-eight. In four of the cases insanity also developed, assuming the form of dementia, and differing in degree and corresponding to the dementia resulting from organic brain-disease.—*American Journal of Insanity.*

**BRIGADE-SURGEON LIEUTENANT-COLONEL
JOHN MARTIN COATES, M.D., F.C.U.**

THE news of the sudden death of PROFESSOR J. M. COATES will be received with universal regret throughout Bengal and other parts of India. For nearly forty years he served in various appointments and in almost all the large stations in lower Bengal.

DR. COATES was born in County Down, Ireland, on the 6th of July 1832. His father's family came originally from Yorkshire, and had been settled in Ireland for several generations. He received his preliminary education, and also his medical training in Belfast. He graduated in the Queen's University, Ireland, competed successfully for the H. E. I. Co.'s Medical Service, and obtained his commission as an Assistant Surgeon on the 4th August 1855.

He landed in India in March 1856, and spent the first few months of his service in Baraich, in Oudh. Towards the end of that year he was offered an appointment in a regiment at one of the favorite stations up-country, but before joining, a brother officer who had been posted to the 1st Military Police Battalion, afterwards known as RATTRAY'S Sikhs, asked him to exchange, as he had friends up-country. COATES consented, having, as he used to say in relating the circumstances, no friends in India, and being indifferent as to where he was posted. The exchange turned out to be a fortunate one for him, as in the following year, when the mutiny broke out, the regiment to which he would have been posted, joined the mutineers and the surgeon was among those massacred. Throughout the mutiny DR. COATES served with RATTRAY'S Sikhs, and was present at the relief of Oudh, and the subsequent operations in putting down the rebellion in Behar and Gya. The following incident, which took place during the pursuit of the Koer Sahib, is characteristic of the man. The troops came up with the mutineers who were occupying the famous old fort of Rotasgarh, near Sasaram, and encamped before it. Having seen to his patients, DR. COATES took a book and went for a stroll; becoming engrossed with his reading, he wandered from the camp, and being suddenly startled by two bullets whistling past, awoke to the fact that he was close to the walls of the fort. He turned back, but finding to his surprise that no more shots followed, determined to explore further and discovered the last of the rebels leaving through the opposite gate of the fort.

During his recent visit to Gya, it was a great pleasure to him to go over the ground familiar in the days of the mutiny, and to point out the sites of the fights and skirmishes of 1857-58.

After the mutiny, he was appointed Civil Surgeon of the newly-formed district of Champaran, and while there, he made valuable observations on leprosy, distinguishing the different varieties of the disease. He also contributed a very interesting report on this subject in connection with the enquiry instituted by the Royal College of Physicians, of London.

He did a great deal of surgery at Champaran and was a very successful operator. A few years ago, he shewed a box full of vesical calculi which he had removed while in that station. He was very popular among the planting community, and to this day the older residents speak of his many acts of kindness. It is told of him that he rode 128 miles in one day to obtain the services of a clergyman for one of his dying patients. From Champaran he was transferred to Cuttack, Hazaribagh and Moorshidabad, remaining a few years in each. In 1873 he was appointed joint-Civil Surgeon of Simla; which post he gave up in the following year, on being offered the Sanitary Commissionership of Bengal. While holding the latter appointment, he repeatedly travelled over the whole of the province on inspection duty—a remarkable feat in those days of scant railways and bad roads. DR. COATES was noted for the rapidity with which he managed to get over the country. He travelled with the lightest of gear, and was content to put up with the barest necessities. In his reports he laid special stress on the importance of improving the supply of drinking water, and on the necessity of special precautions being taken against the fouling of wells and tanks used for drinking purposes.

From 1866 to 1871 the late DR. COATES was superintendent of the jail at Hazaribagh, and during these years no man could have done more for the comfort and reformation of the unfortunate men under his charge, than he did. He appeared to have accepted the lines of Burns as his motto for jail discipline—

"Even you, ye hapless crew, I pity you;
Ye whom the seeming good think sin to pity
Ye poor, despised, abandoned vagabonds
Whom vice has turned o'er to ruin."

At the same time, in all reformatory discipline DR. COATES was strict, albeit just. But the nature of the man induced him to consider reformation a higher duty than punishment. Says a writer:—If I were to mention one-tenth of the good he did during these years, I should fill pages. In those days the present Reformatory School in Hazaribagh was a penitentiary for European prisoners, and there were from 80 to 100 persons confined in it when DR. COATES took charge. It was then anything but a Reformatory, and it would have carried off the palm as one of the most demoralising institutions in India, though there was no lack of punishment. These punishments had culminated in two suicides and an outbreak amongst the European prisoners that nearly ended in the murder of the superintendent and jailor. An investigation was held, and both the superintendent and jailor were removed. DR. COATES was appointed to take the place of the former and he soon shewed that he was both a reformer, and a leader of men. The first thing he set about was a classification of prisoners, and the provision of some rational mode of employment for them, instead of the demoralising one of digging holes to-day, to be filled up to-morrow. At that time there was a large number of men in the jail—soldiers and sailors who could neither read nor write. For these DR. COATES opened a school, selecting a schoolmaster from among the educated prisoners. But as our paternal Christian Government had not made any provisions in their jail budget for such an institution

as a school, DR. COATES had to spend his own money in order to provide reading books, copy books, slates, etc. But that he did not grudge, and the jail school soon became a reforming and flourishing institution. He next determined to form a library. There was not such a thing as a Bible or a Prayer Book in the jail at this time, but DR. COATES soon had every man supplied with a Bible, Church Service, and Hymn Book; and for days, when not otherwise employed, he would be riding round the station on his old horse "Bob," soliciting contributions of books for his jail library. He also wrote to friends and acquaintances, far and near, asking them to collect books, and send them by bullock train parcel to him, the freight for which he mostly paid himself. He even laid SIR WILLIAM GREY, then Lieutenant Governor of Bengal, under contribution for a donation of books for the prison library. Whilst doing this, he laid out the grounds in each ward of the prison into beautiful gardens for the cultivation of fruit trees and vegetables; in this also he largely spent his own money for plants and seeds. In less than twelve months, crime was almost unknown in the prison. Every Sunday DR. COATES saw the prisoners paraded for Divine Service, which he always attended himself, after having first arranged for places for both Protestants and Roman Catholics to hold such services. He also established a voluntary Sunday afternoon school, which was usually well attended. The doctor used to mark out the lessons himself, and to write out short but pithy commentaries on the lessons, when he could not attend the school himself. His next great anxiety was to find employment for discharged prisoners who were neither soldiers nor sailors, and many an unfortunate man has to thank the good doctor for assisting him to a fresh start in life.

"But DR. COATES' good work suddenly came to an end in 1871. When SIR GEORGE CAMPBELL succeeded SIR WILLIAM GREY as Lieutenant-Governor of Bengal, he paid his first official visit to Hazaribagh in the autumn of 1871, and in due course inspected the European Penitentiary. In going round with DR. COATES, who, with a just pride, was shewing all his reformatory arrangements, SIR GEORGE CAMPBELL turned round like a hyena, and snarled out, "I did not come here to see a hotel! I came to see a place of punishment, and of that I have seen none." That night the decrees went forth that the jail gardens were to be rooted up. "Fruit trees inside a jail! What next?" said SIR GEORGE. The school was at once closed, the library broken up, and the books sold. "Who passed the bills for such an assortment of books?" DR. COATES tried to protest, and pointed out that the books had not cost the State one pie, and that all that he had done for the prisoners had received the sanction and support of SIR WILLIAM GREY and DR. MOUAT, who had just retired from the position of Inspector-General of Prisons. DR. COATES even pointed out that one of the books, which SIR GEORGE CAMPBELL objected to, bore an inscription to the effect that it had been presented by SIR WILLIAM GREY to the Hazaribagh Jail Library. But, as the missionary who writes the reports of the Bethel Mission at Jaintara would say, "the devil was in power, and chuckling in his sleeve" behind SIR GEORGE CAMPBELL, who snarled back at DR. COATES: "Convicts are sent to jail for punishment, not to

Yours Truly
J. M. Bates

be stuffed with Mark Twainism"—the book objected to being one of Mark Twain's productions. The result was that, rather than carry out SIR GEORGE CAMPBELL'S drastic system of jail discipline, DR. COATES resigned his appointment as superintendent of the Hazaribagh Jail, at much pecuniary loss to himself, and went as civil surgeon to Berhampore. SIR GEORGE CAMPBELL had little difficulty in finding a jail superintendent according to his own heart, and good DR. COATES took leave of his prisoners with tears in his eyes, when handing over charge. The European penitentiary of Hazaribagh once more became a hotbed of demoralisation, and before twelve months had elapsed, among about eighty prisoners, mostly young men of good physique, there were six deaths, two of which were suicidal, two desperate attempts at suicide, and one attempt at murder for which a man was tried in the Calcutta High Court. So much for Europeans. The floggings in the native jails became so numerous that the total lashes in one jail averaged fifty for every prisoner confined in it, and the death-rate became so high that even SIR GEORGE CAMPBELL himself became afraid of consequences, and tried to throw the blame on the jail superintendents, some of whom retaliated by threatening to publish his own written instructions. This however is not a history of SIR GEORGE CAMPBELL'S jail mal-administration, but a chapter from the life of the late Brigade-Surgeon J. M. COATES."

In 1877 he officiated as Principal and First Physician, and Professor of Medicine to the Calcutta Medical College and Hospital, and in 1880 he was appointed substantively and continued in this appointment until he retired in 1890. During his principalship many important changes were made in the College and in the Hospital. He was a warm advocate of female medical education, and took a large and active part in establishing the female class at the Medical College. His interest in the members of the female class continued long after they had left the College, and he was ever ready to assist them with his advice and purse.

In the Hospital many important improvements were carried out, the Eden and Ezra Hospitals were built, and the system of nursing greatly improved under his régime. During the time he was Principal, he had a very large consulting practice, and his opinion was greatly valued by all, especially in Indian households.

Fourteen years of a connection with the Medical College brought DR. COATES into intimate relationship with almost every independent physician in the city. He will long be remembered by his non-official brethren as one of the most painstaking, practical and level-headed consultants, while his hearty and congenial manner made it a positive pleasure to have professional intercourse with him. Unlike the majority of his official cloth, he saw no social distinction between the official and the non-official, and his presence as a congenial visitor in the home of many a private practitioner, gave him a warm place in the hearts of them all.

To the local profession his death is a very personal loss, and the presence of so many hard-worked private practitioners, both European and Indian, to pay their last respects to his memory at his open grave, was a touching evidence of the esteem and affection in which DR. COATES was held by them.

His long tenure of office as chief physician to the Medical College Hospital brought him in contact with the poor and stricken. Towards these suffering ones the genuine magnanimous sympathy so characteristic of the man, was evinced in all its sweetness. He was essentially the poor man's friend. Those who knew him best and saw countless instances of that quiet unassuming charity which keeps secret the doings of a heart full of humanity, might record volumes of his benefactions to the indigent and helpless when they were leaving his kindly care from the wards of the hospital. How many a poverty-stricken home in this city mourns the absence of this great philanthropist. How many such homes will now recall the smiling encouraging countenance that brought sunshine and hope by the return of fees and by his refusal to receive remuneration for his services when he knew the acceptance of a well-earned fee would mean discomfort and perhaps starvation to those who offered it.

As a teacher DR. COATES was thoroughly practical. He was no orator, and his utterances in the hospital clinic were crudely to the point and very often humorous in their peculiar applicability. He was loved by his students, who were all "his boys," and his interest in their welfare was not of a passing character; for his influence and help were always at the disposal of his students, even after they had left the portals of the College.

DR. COATES had a wide reputation of being a very skillful physician, possessing great knowledge of the diseases of this country. It is much to be regretted that he did not record his experiences—a want of leisure preventing his doing so.

During his services in Bengal, he received the thanks of Government on four occasions: the first time was in 1867 for services rendered during the Orissa famine; the second in 1875, for services during the Behar famine; the third for services rendered during the cyclone of Noakholly and Chittagong in 1877, and lastly in 1879 for his work in the Committee on Medical Expenditure.

In 1885 he was employed as President of a Committee of Enquiry into the sanitary aspects of the Kidderpore Docks and the neighbourhood of Tolly's Nulla.

In 1886 he was offered promotion to the administrative ranks, but being greatly interested in his work, and having many ties in Calcutta, he preferred to remain Principal of the Medical College to the end of his service. After his retirement in 1890 he travelled in Cashmere, where his services were availed of by the Maharaja. Subsequently he accepted the post of Physician to the Maharaja of Durbunga, which he resigned last year and went home, visiting China, Japan and America on his way.

During his career in India he numbered among his patients many of the highest Indian families, and with all of them he was on terms of intimate friendship.

Having briefly noticed the principal events in the life of DR. J. M. COATES, we may conclude with an extract from a letter by an Indian friend who knew him intimately: "He was one of those sincere friends of the natives of this country whose sad loss will be mourned by a wide circle of his admiring friends. It will be very difficult in these hard times to replace him. His kind and benevolent disposition, his deep religious conviction, his ever cheerful temper, his ready humour and wit, will long be remembered and appreciated by his many friends and acquaintances."

THE Indian Medical Record.

1st August, 1895.

SIR WILLIAM ROBERTS, MD., F.R.S., ON THE
GENERAL FEATURES AND THE MEDICAL
ASPECTS OF THE OPIUM HABIT IN
INDIA AND THE RECKLESSNESS
OF THE EVIDENCE ON WHICH
HIS CONCLUSIONS ARE
BASED.

II.

THERE is yet one feature of the relation of the opium habit to malaria in Bengal which we must not overlook, before proceeding to consider the remaining sections of the memorandum, by the medical expert with the Royal Commission on opium, *viz.*, the relation which age bears to malaria and the opium habit.

Apart from the habit of giving opium to infants—which is quite unknown in rural Bengal, there is a consensus of opinion that opium-eating is usually begun about middle life—40 to 45 years of age. SIR WILLIAM ROBERTS says: "The opium habit is mainly a habit of middle life and advancing years, and Dr. CROMBIE even admits the same, when questioned by MR. FINSHAW—

Question: "You state that the opium-eating habit is a habit which is taken up in advanced life—this remark applies to Eastern Bengal?"

Answer: Yes, to Eastern Bengal, and Calcutta."

If we examine the statistics of any dispensary relating to out-door malarial fever patients who come to our dispensaries for relief, in any of the malarial districts of Bengal, we find that the incidence of malarial fevers falls most severely on the ages of infancy and childhood—from 1 to 12 years of age; childhood being the period of greatest mortality, as it is the period of least resistance to the malarial poison.

In malarial Bengal, therefore, one would expect that if the prophylactic properties of opium were known at all to the people, it would be found as a household remedy for childhood and youth, to arrest excessive mortality or mitigate the untold suffering and misery inseparable from the malarial environment. Instead of this, we find, as already stated, that the habit is unknown among children, and as Dr. CROMBIE admits, is mainly a habit of "advanced life," presumably begun by those whose constitutional fitness and social comforts have enabled them to survive the fatal periods of childhood and youth. Even if we could grant that the habit is common among middle-aged ryots—which it is not—an opium-eating parent, finding the drug beneficial to himself, would surely not withhold it from his suffering offspring—to do so would be "a wanton cruelty!" indeed, but we neither find the parents nor the children of the poor ryots of Eastern Bengal using the drug for any such purpose.

We must apologise to local medical men in Bengal for being obliged "to slay the slain" and to drive this silly phantom of "opium as a prophylactic" into the congenial atmosphere of fiction from whence it at first emerged:

lest otherwise those who are unacquainted with Bengal might believe that there was some truth in the statement so diligently put forward by official witnesses that opium was used as a prophylactic against malaria by the ryots of Bengal. We thus see that the malarial theory as the cause of the opium habit, utterly breaks down in the most malarious province in India—when brought to the test of ascertained facts and figures available to any medical man who knows Bengal and the Bengal ryot.

III. *The practice of giving opium to infants.*—This is undoubtedly the saddest and most painful feature of the whole subject of opium-eating in India. The callous indifference and seeming lightness of heart with which this cruel and barbarous custom is treated by the medical expert, afford food for reflection to every lover of species. He says: "In Bombay children's pills or 'balagolia' are extensively sold for this purpose. These pills are now manufactured in order to insure purity and constancy of strength, and contain respectively, one-sixth and one-third of a grain of opium each, mixed with a variety of harmless spices." "The practice is an ancient one, and prevails extensively all over India, but especially in the North-West Provinces, in the Native States of Rajputana and Malwa, and in the Bombay Presidency." That the practice is *not* prevalent "all over India" we have already shewn, for in the malarial swamps of Lower and Eastern Bengal the habit is unknown. Not only does SIR WILLIAM ROBERTS advocate non-interference in this criminal practice, but he tacitly acquiesces in the custom as "harmless" and "sometimes beneficial." But he is not the only one who approves of this mode of increasing infant mortality: even the parental Government of Bombay itself—(supported, we are ashamed to add by the approving certificate of Surgeon-Major PARKER who reports "that though the practice of using opium pills to quiet children may be open to objection, it is inseparable from native habits and customs," and that the pills are "comparatively harmless") has undertaken the manufacture of those pills under the supervision of the licensed vendor! The habit seems to cling almost exclusively to the inhabitants of past or present opium-growing centres, and adjacent cities, where illicit opium can, or could at one time be easily obtained. The responsibility for the introduction and fostering of this cruel habit with all its ghastly train of infantile suffering must be laid at the door of those who permit and foster opium cultivation in India. We need not go into details to prove that the practice is fraught with the most disastrous consequences to infant-life leading to marasmus, disease and death. SIR WILLIAM ROBERTS, as a physician, knows full well that "in childhood the brain is proportionally larger than in adult life, hence the effect of opium is greater than in adults, and children bear it (opium) very badly: consequently, smaller doses must be given than are proportionate to their ages. Care is necessary from the age of 6 months to 1 year, as one minute has produced fatal results" (BENTON). He himself tells us that another tendency of opium consumers is to grow "unduly thin," or in more forcible medical language, to become emaciated by arrest of nutrition. "All the secretions of the body, except those of urine and sweat, are lessened by opium" (BENTON). Here then we have two universally admitted properties of opium: (a) its more powerful action and greater danger in

infant life ; and (b) its general arrest of nutrition, even in adult life, much more so in infant life. With the knowledge of these facts before him, the medical expert writes of this criminal practice approvingly as follows : " Indian mothers and nurses, and the native public generally, have an unquestioning faith in the wholesomeness of giving opium to children, and the accumulated experience of successive generations of parents extending over hundreds of years, furnishes a body of presumptive evidence which is not to be lightly set aside on the ground of *a priori* considerations." He thinks it is " not on the whole injurious to any appreciable extent."

The above argument might have some soundness were it applied to intelligent mothers educated and trained in morality and in the sacredness of family life ; but utterly inapplicable to the condition of the poor, ignorant, custom and caste-bound mother, who neither knows the dangers of the drug, nor the guilt of mishap to her infant ; or if she knows the danger disregards it, under pressure of want or the plea of dire necessity to maintain herself and her children. She must be free to work for food for their support, and her infant can only let her free by being kept daily, for long intervals, without food, under the influence of the drug.

It is the natural result of the conditions of this kind of infant life that the child should sooner or later, if not overdosed to death, present the pitiable picture we are familiar with, in regions where the habit prevails. The feeble attempt made by SIR WILLIAM ROBERTS to account for the atrophy of opium-drugged infants by quoting PROFESSOR HENNOT'S description of an atrophied child—from tuberculosis, syphilis, or general inanition—is not to the point. It was told, by one independent medical witness at least, that the atrophy of opium-eating infants disappeared when the drug was withheld—" the child recovered health and plumpness." It is only evading the point at issue to direct the reader's attention to a different condition—which only in rare instances simulates the atrophied opium-baby,—the real nature of which any competent medical witness would not fail to detect.

Even if we accept DR. ARNOTT'S opinion—on which so much reliance is placed in the report—we have enough to prove the deleterious effects of the drug on infant life, and the high mortality among infants, for which it is responsible. While endeavouring to shield the practice, he nevertheless says:—" But others, (opium-infants) ill-fed, ill-cured-for, are emaciated, and no doubt among these last there is a large mortality." We would ask any one, who knows the conditions of grinding poverty under which these poor mothers live, to consider the utter impossibility of her giving due attention to her infant, and supplying it with its full share of natural nourishment when she must keep it under the influence of opium in order to set her free to work for the rest of the family. Should fortune so favor her as to place her in a position of comfort, where she could afford nourishing food for her infant, of what use would it be to the child, if it has to struggle with the emaciating power of the drug, and only receive its food at long intervals when not under its influence? Under such conditions the opium-eating infant lives, moves, and has its being ; and we can expect nothing else than speedy marasmus and inanition to follow, until at length nature

yields, death relieves its sufferings, and puts an end to its poor troubled, tortured existence.

The excessively high mortality among opium-drugged infants is thus airily passed over in the medical memorandum:—"It was shewn that accidental poisoning sometimes attended the practice, children were occasionally brought to the dispensaries in a state of somnolence or coma from accidental over-dosing by a mother, or from a child getting hold of a lump of opium or a box of "bala-goli" pills left carelessly about and so poisoning itself.....Some of the medical witnesses expressed a doubt, whether fatalities from this cause were more frequent in India than occurred at home from opium given to children in the form of soothing syrups and cordials dispensed under medical prescriptions (!) DR. BLANEY, who was Coroner of Bombay for 17 years, could only recall five or six fatal cases of infants being accidentally poisoned in this way." The reason why the excessive death-rate among opium-eating children is not shewn in urban municipal or rural statistics is very simple. Let us describe a case which will serve as a type of hundreds of cases.

A coolie woman, the wife of a field laborer, gives her child an overdose of opium and the child dies. She feels guilty and afraid of the police. She must conceal the real cause of death from the authorities, lest she be put to great trouble and expense, and be subjected to endless worry by the police, who will extract her last pice from her, by keeping the terror of prison before her. What is she to do? She simply says her child died of fever, or bowel complaint, or some other common ailment and there is no more about it. In 99 cases out of the hundred, the opium-death statistics, even within Municipal limits, are never swelled by these cases. If the death occurs outside Municipal limits in rural tracts, no one asks and no one cares to know why the child died ; and no report ever reaches the thanah or police station—4 annas will protect her from that annoyance—the chowkidar or village watchman merely reports a death from some prevailing ailment, or more frequently takes no notice of it whatever. *It is a matter that calls for explanation why Sir William Roberts and his advisers, while knowing these facts, for they are known too well to every medical officer in India—should have palmed off on the non-professional members of the Royal Commission, and the British public, worthless and utterly misleading statistics of infant mortality from opium-eating in India.* To quote DR. BLANEY, 17 years coroner of Bombay as saying, "that he could only recall five or six fatal cases of infants being accidentally poisoned in this way," is audacious in the extreme, in the light of the above popular methods of recording opium-deaths. We can only account for it by the certain expectation that no medical officer in India would dare reveal the true state of affairs ; and that the British public were neither competent enough, nor sufficiently interested in the subject, to perceive the hollow and unreliable nature of the statistics referred to. "To European ideas," writes SIR WILLIAM ROBERTS, "the practice seems objectionable. The surroundings of child-life in India, are however so peculiar in relation to domestic circumstances, to food, climate and malarial influences, and as regards the exceptional tolerance for opium of

Indian infants that it would not be safe to judge the custom by European standards."

In the above extract there are two outstanding errors: (1) the habit is attributed to, or excused on the ground of malarious influences: (2) the writer assumes,—although repeatedly told to the contrary,—that Indian infants have "exceptional tolerance" for opium. As already stated, the habit of giving opium to infants is not known in the most malarious districts of India, *viz.*, Lower and Eastern Bengal, where children have the malarial taint from infancy. And that European children can bear opium as well, if not better, than native children is not a matter of opinion, but of actual experience. The theory of a "profound constitutional difference" or "exceptional tolerance" in the adult natives of India and their children is omnipresent in SIR WILLIAM ROBERTS' memorandum; but it finds no favor with two of the most influential medical witnesses put forward by the Indian Government. SIR WILLIAM MOORE,—an undaunted champion of the beneficial effects of opium on every other person's children except his own:—says "I do not think the constitutional difference has anything whatever to do with it," and SUGGON-MAJOR GENERAL RICE declares emphatically that "I have satisfied myself in my professional practice that Europeans are more tolerant—that is, require larger doses of opium, than natives bulk-for-bulk." These clear statements are in accord with the experience of medical science all over the world: there is absolutely no racial peculiarity distinguishing the natives of India as regards tolerance for opium, and although this fact entirely controverts SIR WILLIAM ROBERTS' theories, it remains still a fact, which any medical practitioner can test for himself. It is true that DR. CROMBIE, when asked the leading question.—"Do you think the people of India have a peculiar tolerance for opium?" replied "I have reason for believing that there is such tolerance." From what we have already learned of the careless inaccuracy of this witness, we may safely disregard his isolated statements on this subject, as conflicting with the experience of most, if not all, independent medical practitioners in India.

But when DR. CROMBIE was cross-examined on this point and asked:

Question: "Do you think that opium has less effect upon people here than in England?" he replies.

Answer: "I am not quite sure of that!"

Suicide—its relation to opium. There is no feature of the opium question in India which strikes a stranger,—who reads the daily press, so forcibly as the frequency of opium suicides in our large cities, especially Calcutta. The official and non-official witnesses before the Commission were unanimous in their testimonies regarding the excessive number of suicides that occurred by means of opium. But the medical expert with the Royal Commission on opium drops this unsavory subject with a passing notice of twenty lines of printed matter, and provides amusement for Indian readers by quoting provincial statistics, which are as worthless as they are inaccurate, for showing the prevalence of suicides by opium in India. He writes,—"Some of the witnesses expressed the opinion that the opium-habit in India was provocative of suicide." We expect scientific clearness and exactness of expression in a memorandum written by a medical expert with a Royal

Commission, and cannot therefore understand why the above sentence has been penned. We have read over most of the evidence,—carefully we confess,—of the most important medical witnesses who came before the Commission, but we are not aware that any one of them made the careless statement attributed to them in the above sentence. The statement (2605) quoted by SIR WILLIAM ROBERTS as giving expression to this view, says nothing about the "opium-habit." The quotation is as follows:—"One of the witnesses contended that opium 'is of all poisons the one which must be most attractive to a suicide. It presents death in its easiest and most delightful form to one who has reached that state of mind. I believe that its free sale does greatly encourage suicide.'" There is no mention here of the opium-habit in India" being "provocative of suicide." On the contrary, every witness who referred to this subject at all, stated clearly that the cheapness of opium and the facility with which it was procurable for criminal purposes were "provocative of suicide." Professor J. F. P. McCONNELL's (of the Calcutta Medical College) evidence is conclusive on this point:—

Question: "You say it is necessary (restriction of sale) to prevent the occurrence of suicide?"

Answer: "The number of cases of suicide by opium is very great," &c.

No one who knows the effect of opium on those who are addicted to the habit would expect that it would lead them to suicide. The opium-eater is by the habit rendered weak, nervous, timid and irresolute, and rarely attempts to commit suicide; and he knows well, that if he did so, his acquired tolerance for opium would render the issue doubtful. On the other hand, to those who know the fatal properties of the drug, but are unaccustomed to its use, it offers a pleasing, painless and seductive mode of death. To prove that this view is "not supported by an examination of the official statistics of suicide in the different provinces of India," the medical expert gives the following table:—

| PROVINCES. | Total annual suicides per mille of population. | Proportion of suicides by opium to total suicides. | Annual average consumption of opium per head of population. |
|---------------------------------------------------|------------------------------------------------|----------------------------------------------------|-------------------------------------------------------------|
| North-West Provinces and Oudh, average of 5 years | 61 | 18.5 % | 24 grains.* |
| Madras Presidency ... | 54 | 0.05 " | 14 " |
| Central Provinces ... | 49 | 2.4 " | 34 " |
| Bombay Presidency and Sind, average of 4 years | 46 | 9.5 " | 46 " |
| Bengal, average of 5 years | 39 | 11.1 " | 15 " |
| Punjab, average of 5 years | 24 | 9.0 " | 42 " |
| Assam, average of 8 years | 20 | 5.0 " | 141 " |

That this table of statistics cannot be accepted as even approaching to accuracy regarding opium suicides, will be made clear by the following facts regarding Bengal and Calcutta. The following quotations are from the most recent, reliable and authoritative statistics collected by DRS. EVANS and CHURN LALL BOSS in their joint paper read before the Indian Medical Congress at Calcutta.†

It is generally admitted that in the matter of statistics Bengal is farther advanced than any other province in India; yet of Bengal the authors say:—"We regret, to say

* North-West Provinces only, Oudh is 15 grains per head.

† The necessity for an Act restricting the free sale of poisons in Bengal.—L. M. R., Vol. VIII, 4, pages 172, 173, &c.

that no returns are available for the whole province of Bengal to show what proportion of suicides is due to violence and what to poison; nor are all the cases of suspected suicide by poisoning that occur, referred to the chemical examiner."

After stating the excessive number of suicides by poison in Calcutta—"for the five years 1889 to 1893—236 cases occurred or an annual average of 68·84 per million. Of these cases 23 were due to arsenic and 167 to opium and 46 to other poisons;" they ask: "Is there any reason to suppose that suicide by poison is more frequent in the large towns of Bengal than in rural districts?" They answer in the affirmative with the following judicious reservations:—"It is possible, however, that a considerable number of cases of suicide by poison occur in rural districts, that are never reported to the police or brought to light in any way. Instances of suicide also occurring in families of respectable and influential individuals are no doubt often secretly disposed of to avoid scandal." It may be added that in many rural tracts of Bengal opium shops do not exist, and the drug is therefore not conveniently at hand for suicidal purposes,—in such tracts, although suicides by violence and from other poisons may be numerous, those from opium will be less frequent. On the other hand, in opium-growing districts, or districts in the vicinity of which opium is cultivated, the drug is always at hand—in these districts the great majority of suicides will be opium-suicides. We are of opinion that if it were possible to obtain correct statistics of opium-growing districts such as Gaya, they would clearly indicate that opium suicides bear a very close relation to the cheapness and accessibility of opium in rural districts. But Drs EVANS and BOSE inform us that,—“At the present time, the available statistics afford no information as to what proportion of the total suicides occurring in the province are due to violent methods, and what proportion to the use of poisons.” If they were obliged to write as above regarding the statistics of suicides in the province of Bengal, how much less reliable must be the statistics which refer to the other provinces of India. But the author of the Medical Memorandum, nothing daunted by these difficulties, proceeds to prepare Table IV, which he compiled, he tells us from the “total suicides in the several provinces of British India.” In other words, the very provincial statistics of which Drs. EVANS and CHUNI LAL BOSE write—“the available statistics afford no information” are precisely the figures upon which he relies to prove that the proportion of opium-suicides to the total suicides in the province is only 11·1 per cent! And that there is no “connection between the amount of (*licit*) opium consumed in a province and the prevalence of suicides in that province—this latter statement, as we have already shown, no one maintains. Let us examine these figures more minutely: (1) We may lay it down as incontrovertible that in no district of Bengal are all the suicides reported; it is only when crime is suspected that suicides are brought for *post-mortem* examination. (2) In opium-growing districts, such as Gaya, opium-suicides form 80 to 90 per cent. of the total suicides reported. (3) In such (opium-growing) districts every cultivator has his own stock of *illicit* opium always at hand; he therefore does not use

licit opium at all, hence the consumption of *licit* opium in these districts is represented by a mere fraction of grains per head per annum thus:—

| | | | | | | |
|-----------|-----|--------|-----|------|-----|--------|
| Champanan | 8 | grains | per | head | per | annum. |
| Saran | 9 | " | " | " | " | " |
| Shahabad | 2 | " | " | " | " | " |
| Mongyr | 2·4 | " | " | " | " | " |
| Gaya | 5·2 | " | " | " | " | " |

Were it not that there are a few towns like Gaya scattered over these districts—where opium-eaters are obliged to buy, sometimes, small quantities of opium—there would be no *licit* consumption at all shown in the official statistics. Would it be in accordance with facts, as we know them, for us to infer regarding these opium-growing districts that there is little or no opium consumed in them, because the official returns for *licit* opium are so low? Surely not. Yet this is one of the inferences Sir WILLIAM ROBERTS' statistics would lead to. These opium-growing districts of Bengal, and presumably of other provinces in India, show only a fractional opium consumption per head per annum, with 80 to 90 per cent. of opium-suicides out of the total suicides from poisons!

The Commissioners themselves had no such thoughts in their minds regarding these low averages; for they point to the fact of opium cultivation as an explanation of the low average consumption of *licit* opium in opium-growing districts. In other parts of rural Bengal vast populations exist, where opium is not grown nor used largely, and among them *opium suicides* are not so frequent, as the drug is not conveniently at hand. We thus see, that for rural Bengal, the official provincial statistics cannot be accepted as a safe guide, because they do not distinguish between suicides by violence, by opium, and by other poisons; nor can the actual consumption of opium be ascertained in opium-growing centres, because of the universal use of *illicit* opium in these districts. Those difficulties and discrepancies in themselves would utterly vitiate the provincial statistics, and render them not only worthless, but positively deceptive and misleading.

But happily we are not left wholly in the dark regarding opium-suicides in Bengal, for we have fairly accurate statistics for the town and suburbs of Calcutta, which will throw some light upon the figures for the whole province.

Drs. EVANS and BOSE—to whose able paper we are indebted for the following figures and facts regarding Calcutta, state:—

“Among the population dwelling in the Municipal area of Calcutta during the years 1st June 1893 to 1st June 1894, 52 deaths by poison occurred, of these 44 (all suicides) were due to opium, or 84·6 per cent. Also that of the total number of cases of poisoning,—165,—brought for treatment to two Calcutta Hospitals—Medical College and Mayo Hospital—94 cases were cases of opium poisoning, or a proportion of 57 per cent. as compared with all other poisons used in these cases. These percentages of opium suicides are considerably higher than “11·1 per cent.” We do not however forget that these high percentages of opium-suicides within the Municipal limits of Calcutta are not obtained in rural districts, such as Eastern and Lower Bengal proper where opium is not cultivated and little used by the

people; but we do maintain that in opium-growing districts or wherever opium is cheap and easily accessible, the percentage of opium-suicides to suicides by all other poisons will be found even higher than 84.6 per cent.

It is the cheapness and unrestricted accessibility of opium, together with its soothing, painless, hypnotic properties, that account for its more frequent use for suicidal purposes than other poisons. These views are not "anti-opium" views; they are put forward by the officials above referred to as follows:—"Since the easy accessibility of poisons is responsible for a large number of suicides, it is this very easy accessibility of poison which should first be dealt with by legislative interference. Opium has been shewn to be responsible for the majority of cases of suicide in the Municipal area of Calcutta, whether by violence or otherwise, and opium is to be found in any quantity (in licensed shops) every-where throughout the country."

And "that taking the results of ten years as the basis for the calculation, opium and arsenic constitute 90 per cent. of the poisons detected. Opium by itself is the poison detected in 58 per cent. Then bearing in mind the statement already made regarding these cases of opium-poisoning, this figure, viz., 58 per cent., may be regarded as indicating the conditions influencing poison selection in cases of suicide by poison throughout the province."

Then in support of their views that the use of poison for suicidal purposes is increasing they say (a) "That the crime of self-destruction has enormously increased during the last ten years, and that the cases which have produced the increase are almost entirely those of suicide by poison; for while during the five years 1876 to 1880 the average of suicide by poison to the population was 36.42 per million, in the period 1889 to 1893 it had risen to 68.84 per million, or nearly double. (b) Of 100 cases of suicide occurring in the town and suburbs of Calcutta, 56 are due to poison; and of the 56, in 40 opium has been the poison taken (or opium 71.4 per cent. of total poison) in 5 arsenic, and in 11 other poisons."

These are our reasons for rejecting "Table IV" constructed by Sir WILLIAM ROBERTS from provincial statistics, reasons which are patent enough to any one familiar with Bengal—and they prove we think beyond cavil or doubt that the average suicides and average opium consumption taken from provincial statistics are utterly untrustworthy. With these explanations, and emendations, we can even agree with Sir WILLIAM ROBERTS when he says:—"Nor is there any connection between the amount of (*licit*) opium consumed in a province and the prevalence of suicide in that province," for no one, so far as we are aware, has given expression to any such crude and inaccurate statement before the Royal Commission on Opium.

THE PHYSICIAN AS A MORALIST.

THE ideal physician is an embodiment of so much knowledge combined with so many qualities and virtues that it is hardly to be expected that any age can have the proud distinction of possessing more than isolated examples of such men, or that the world's history will be adorned with anything more than a few scattered specimens of such. It is well, however, at times to

contemplate such an ideal; for such contemplation may lead to the attainment of at least some of those qualifications and endowments which enrich the ideal, and ennoble our profession. One among the many of those considerations is that of the physician as a moralist; and it is as such that we propose to view the model man of our noble calling. As a moralist the physician has ample scope and special opportunities for effecting good among every sort and condition of men. Youth and age alike require his moral counsel. With the individual he possesses an influence, and to the nation he is a material help, if not a necessity, in fashioning the coming man or in benefiting a people. From the earliest moments of his professional career he has witnessed the results of moral delinquencies, of youthful indiscretions, and of social abuses. Almost every form of ailment points its own moral which can be turned to the advantage of suffering humanity, to the benefit of future progenies, to the improvement of whole communities, or to the amelioration of the condition of a whole nation. The true physician knows that his mission is not limited to the healing of disease and the maintenance of health, but extends to, and is materially concerned with, domestic happiness, social advancement, political good, and the stability of a nation. He sees how diseases are engendered by pandering to one's vanities, or in paying unreasonable homage at the shrine of fashion; he notes the influences for good or ill that the habits of an individual have on the duration of life; he knows the sphere and surroundings in which childhood and youth should be nurtured, in order that they may develop into healthy manhood and womanhood; and he endeavours to minimise those ill-advised and regrettable unions which give promise of unhappiness and of a weakly progeny. In short, he is an adviser in matters not only affecting the well-being of the babe yet unborn, but all along the pathway of existence he endeavours to help his fellow-passengers not only to reach its most extreme limit, but to do so under the most favorable circumstances possible. In almost a countless variety of ways these are the thoughts, words and actions of individuals under the moral direction and control of the physician. As a moralist he is moreover an important and indispensable state help in the administration of justice, and in guiding the powerful arm of the law. How often by his careful deliberations has he not brought home conviction and punishment to the culprit who, by his craft and cunning, may otherwise have defeated the ends of justice? How often has he not rescued the guiltless from the disgrace and ruin which the machinations of unscrupulous persons prepared for them? How often by his care and investigation has he not saved from death at the hands of the executioner, the supposed murderer whose crime after all was not so heinous as it at first appeared? In all these, and in many other ways besides, is the physician a material regulator and controller of crime, and of offences against society; and he is an important factor in the maintenance of a wholesome fear and respect for those laws and enactments framed for the good, the peace, and the security of a people and of a State. From all these considerations the true physician is a most desirable friend; for, as Dr. JOHNSON has said, "the

greatest benefit which one friend can confer upon another, is to guard, and excite, and elevate his virtues ;" and not only does the true physician feel that it is part of his mission to warn and counsel friends and all others with whom he is brought into professional relationship, against the direful consequences of moral errors and of offences against the laws of nature and of society, but he is moreover specially qualified to tender admonition in these matters. In the spirit of patience and resignation with which he often sees physical suffering endured he learns many a lesson which enables him to carry wholesome instruction to other beds of pain, and into many afflicted homes ; for though he may not have been reared in the lap of affluence, or he not himself a stranger to fortune's smiles and the good things of earth, he often sees that

"By woe, the soul to daring action swells ;
By woe, in plaintless patience it exerts :
From patience, prudent, clear experience springs,
And traces knowledge through the course of things,
Thence hope is formed, thence fortitude, success,
Renown—what'er men covet and caress."

Thus do his experiences enable him to impart consolation to the suffering, fortitude to the sick, and hope to the dying ; thus leading them to higher thoughts, creating a spirit of forbearance, and turning the miseries of life to this account, viz., to "quicken and exalt our sense and relish of that more ample greatness, that more exact goodness, that sense of God." In the faithful and zealous discharge of his duties he teaches the important Christian doctrine of universal charity and brotherly love. His untinted efforts are put forth as earnestly in the relief of the rich as of the poor. His hearty sympathy is aroused whether the sufferer be a LAZARUS or a DIVES ; and he begrudges not to hazard his health, strength, nay his very life, in ministering to his suffering fellow-beings. Medicine has given a list of martyrs to science, of which she is rightly proud ; and it has always been the characteristic of her votaries to sacrifice much for the benefit of mankind. In his devotion to duty under the most adverse circumstances, and even perhaps in the most loathsome surroundings, the physician proclaims the truth of CARLYLE'S words that "there is a perennial nobleness, and even sacredness, in medical work."

COMMENTS AND NEWS.

THE WORK OF THE GRANT COLLEGE MEDICAL SOCIETY IN BOMBAY.

WE have not space at our disposal to reprint the reports of the various medical and scientific societies in India, but we appreciate their excellent work, and from time to time keep our readers in touch with their doings. We have much pleasure in noticing the more salient points of the review of the work done during the past year by the Grant College Medical Society, Bombay, as delineated by its President, DR. BHALCHANDRA KRISHNA, at the Annual Meeting held in February last.

The Society has been strengthened by fourteen new members, a total of 174 having been now reached. Its financial condition—an important matter with all working bodies—is encouraging, the total income having been Rs. 1,376-0-5, and the expenditure Rs. 1,214. Thus, with the balance on hand

previously, there are Rs. 662 left in favor of the Society, which moreover holds Municipal bonds to the value of Rs. 1,500, and has been substantially favored with the support of the Maharaja of Kolhapur, the Maharao of Kutch, the Dewan of Palanpura and the Maharaja of Idar, who have endowed the Society with Rs. 300, 200, 200, and 100 respectively. The material support that is from time to time accorded by native potentates to Western medicine is very gratifying indeed. The princely support given to the investigation of chloroform anesthesia by the Nizam of Hyderabad, and the interest that the Maharajah of Patiala is evincing in the investigation of fevers, are important beneficent acts which will hand down the names of these potentates to all generations and ages.

Ten regular, and eight special meetings were held during the year ; and papers of no small interest to the profession were read and ably and thoroughly discussed. The titles of some of these may be mentioned, as those particularly interested in any of them may be benefited to know that they are to be embodied in the report of the Society's Transactions for the year. These are : "Notes on a case of Pityriasis treated with a solanaceous plant named *Solanum Nigrum* ;" "Treatment of syphilitic affections of the eye by subconjunctival injections of perchloride of mercury ;" "Notes on a curious case of skin eruption following vaccination ;" "Lithotripsy in girls under 12 years ;" "The extraction of piles as practised by Native Hakims." The President, we may mention in passing, utters a note of warning against these self-constituted pile-curers, who "not only screw out money from people, but inflict such untold misery on their victims, that sometimes the patients are either rendered miserable for life, or die from the effects of the treatment." The titles of the other papers are "Notes on a case of Acute Nephritis with Uremic convulsions ending in recovery ;" "The radical cure of piles with notes of cases, by injections of pure carbolic acid into the base of internal piles ;" and "Observations on the healthy healing of wounds and the use of simple and inexpensive dressings." DR. KRISHNA deplors the fact that there is now a lack of that interest which the professors of the College formerly took in the Society. Their attendance and contributions are now like angels' visits—few and far between. Much however as the cultivation of friendly relations between all castes and creeds of our profession is desirable, and the co-operation of all its members in the advancement of medical knowledge is to be welcomed, we think that the Society possesses enough of vitality not to be seriously inconvenienced in its development and progress by this withdrawal of professional aid ; and the Society will be able to proudly point to whatever meritorious work it may do as the achievements of indigenous talent. A new departure of the Society is that of inviting an outsider to read a paper at a meeting of the Society. This departure on liberal principles is certainly a happy one. The Society has memorialised the Chancellor of the Bombay University to be permitted the privilege of submitting the names of two members of the profession every year for nomination to Fellowships. The system of electing medical Fellows at present obtaining in India is certainly open to very unfavorable criticism, and if the privilege prayed for by the Society will not set matters altogether right, it at least will very much enhance the chances of real merit being more prominently brought under official ken and consideration.

We have to refer to a few remarks made by Dr. Krishna on the first Indian Medical Congress, which DR. KRISHNA is more disposed to characterize as a failure, rather than a success. The sectarian principles that were introduced into the meeting are likely, on future occasions of the same kind, to make the non-official party unwilling to take part in them ; and this has introduced an element which is

sure to operate in defeating the main object of a Congress, viz., the interchange of varied ideas. We think that with the impressions that non-service men who attended the Congress carried away with them, and the impression which those who did not attend have with good reasons formed, will tend to make the next Indian Medical Congress, whenever it may happen to be held, a very sparse gathering.

The Grant College Medical Society has entered upon its Jubilee year. We offer it our warmest congratulations; and we certainly agree with its President in thinking that the Jubilee cannot be more sensibly and substantially celebrated than by its taking the first steps towards having a College and Hospital of its own. We hope that the members will not lose sight of this excellent suggestion; and that before long the foundation stone will be laid of this monument, to bear testimony to the good work of the Society.

A MENACE TO THE PUBLIC AND TO THE MEDICAL PROFESSION.

We quote from *The Statesman*:—"Before MR. S. D. ROY, Deputy Magistrate of Sealdah, the case against MR. JOHN CROFT, which formed the subject of the recent criminal prosecution against him, was called on for hearing, when it was found that MR. CROFT had failed to enter appearance in Court. MR. OAKLEY, his assistant, here informed the Court that MR. CROFT was ill, and produced a medical certificate, signed by DR. CHAMBERS to that effect. The Magistrate observed that the bare medical certificate would not hold good without recording Dr. Chambers's evidence. The case was adjourned for an hour and MR. OAKLEY was requested to produce Dr. Chambers in court. Later on, the case was resumed, when MR. OAKLEY informed the Court that DR. CHAMBERS declined to attend Court without a summons being served upon him, and his fees paid down. The Magistrate then examined MR. OAKLEY, who deposed that MR. CROFT was lying ill with rheumatism in the Bellevue Hotel. DR. CHAMBERS attended him, and granted the certificate. The Magistrate here granted a warrant for the arrest of MR. CROFT with permission to be released on a nominal bail. MR. OAKLEY submitted that this procedure was an uncalled for hardship.

"Here we have evidence of extraordinary and irregular procedure on the part of a Police Magistrate. The italicised portions of the above quotation reveal two facts. (1) that a "bare certificate" signed by a duly qualified medical practitioner will "not hold good;" and (2) that a doctor must be "produced in Court" before his medical opinion can be accepted. We reiterate that Mr. Deputy Magistrate S. D. ROY's action is extraordinary and irregular. Hitherto in all Courts of law, a duly qualified practitioner's "bare certificate" has been accepted, the High Court and the Chief Presidency Magistrate's Court forming no exception to this practice. But here we find a subordinate judicial officer setting aside the practices of higher tribunals and demanding the fulfilment of certain acts which, while they are in themselves perhaps within the exercise of magisterial power, are fraught with considerable inconvenience to the public and to the individual members of our profession. The Magistrate's conduct, if permitted to pass unchallenged and unrestricted by higher competent authority, will become a precedent for other subordinates overwrought with a sense of their own mightiness, and thus a form of judicial oppression, making itself felt in many objectionable ways, will be exercised on litigants. In the first place doctors will be compelled at much personal inconvenience and worry and loss, both to themselves and to their patients, to attend court, where, as everybody knows, much precious time is fruitlessly wasted.

Then again, in order to attend Court, a doctor can only appear in the capacity of an expert witness, and he can demand any reasonable fee he chooses for the time he loses by attendance at the Court. This adds to the expensiveness of litigation, and is a matter which the public may well seriously consider.

We congratulate DR. CHAMBERS on his refusal to appear in Court on the peremptory demand of the Magistrate, and further, that he caused that gentleman to clearly understand that his professional services would have to be adequately paid for, before they were obtained.

We trust that doctors treated in this perfunctory fashion by law officers will always stand up for their rights and boldly insist upon those rights being respected.

We trust also that the Bengal Government will prevent further irregularities of this nature from being committed, as already complaint has been submitted to the Lieutenant-Governor of an arbitrary line of conduct pursued in this identical case in regard to the legality of the medical certificates of private practitioners.

THE USE OF CHLOROFORM IN LABOR.

THE question as to the justifiable extent to which chloroform should be used in labor has of late been much before the profession. Some maintain that it should not be employed at all in normal labors, arguing that "if a mother is unwilling to take upon herself the pains necessary for maternity, she is unworthy of it, and should not be married." This, and that the pains of maternity strengthen the affection of the mother for her child, and other arguments of a like nature are advanced by some against its use in natural deliveries. Another lot maintain that chloroform should be used exclusively in cases of difficult parturition; while a third set, adhering to the Baconian principle that it is "the office of a physician not only to restore health but to mitigate pain and suffering," would use chloroform in every labour case. Dr. W. B. SPRAGUE, in a paper read before the Detroit Academy of Medicine, reviews the teachings and experiences of obstetricians from the time of SIMPSON; and while concluding that not a single death has ever been conclusively shewn to be due to chloroform in labor, provided it were administered properly, and that post-partum hemorrhages and other dangers imputed to the use of chloroform in labor are fallacious, he summarises the advantages of chloroform anesthesia thus:—

- (1) More rapid dilatation of the cervix. It is useful in rigidity or spasmodic action of the os.
- (2) It preserves the perineum by relaxing the muscles, and allows of more manipulation.
- (3) The mother often restrains the contractions and labor is thus delayed. In these cases labor proceeds better with, than without the anæsthetic.
- (4) In cases of heart disease, when palpitation and dyspnoea are induced, the chloroform quiets the heart and removes an element of considerable danger.
- (5) The exhaustion and shock of severe labor are averted; and the contractile energy of the womb is conserved, thus protecting against post-partum hemorrhage.
- (6) Reflex contractions of the abdominal muscles are more easily induced.
- (7) Amelioration of suffering to the parturient woman.

DR. SPRAGUE finds a physiological explanation of the fact of the immunity from danger in the use of chloroform in lying-in-cases, in the doctrine promulgated by the Hyderabad Commission, viz., that the heart is never affected by chloroform except by over-dosing, and that safety is guaranteed by regular breathing; and as labor pains provoke long, deep, and full respirations, the element of danger is obliterated.

WHO COUNTERSIGNED THE MEDICAL CERTIFICATE?

WHILE Calcutta is ringing with the question, "Who is the official doctor who behaved so badly about the certificate," our contemporary, *The Anglo-Indian*, gives vent to the following comment on the subject:—"The day in which the Indian Medical Service was jealous of the honor of its members must have passed away, and another must have arisen in its place, which is hardly half so full of promise, if a story told by the *Indian Medical Record*, which bears the impress of truth in all its turns, does not inspire the *esprit corps* of the Service to provide some remedy for the evil brought to light. A chance was given to two Presidency Surgeons of countersigning a certificate granted to a Government official by an independent medical practitioner of sufficient standing to make it equally clear to both men that the only strictly professional course open to them was to attach their names to the recommendation of the non-official physician. One man signed the recommendation; the other, not to put too fine a point upon it, didn't. He, instead, without any examination whatsoever, of the patient, beyond that which a glance of his eagle eye, or it may be a scent of his eagle nose, instantaneously effected, made some contradictory recommendation, which might have injured the rival physician, if any particular value attached to his opinion. The more sensible of the two Presidency Surgeons examined the patient, saw that what the non-official doctor had said was the only thing to say, and gave it the support of his signature. The matter is, in one sense, of small importance, but in another, it suggests unpleasant questionings. Of two opposite statements, only one can be true, and adhesion to the other can only mean either ignorance or what Sir Richard Temple once called an "incorrect expression," and other people call by other names. To the general public, if they will take the trouble to think of the matter—which of course, they may not do, since even the vagaries of a Presidency Surgeon possess a royal road to public attention, this conundrum may be presented by the facts: If, of two officers and gentlemen, one behaves as an officer, and the other as a gentleman, which is who?"

MEDICAL CHARITY.

CLOSELY connected with hospital abuse, and as a consequence of it, is the manner in which the medical profession is exploited at the present time. The large amount of gratuitous medical relief given now-a-days, is NOT given at the expense of the so-called philanthropists who subscribe to the various hospitals, but at the expense of the medical staff, by whose gratuitous work the organization of the institution is carried on. The services of any medical man may, now-a-days, seemingly, be commanded by any one, without fee or award, e. g., in coroner's inquests, where, should the summoned doctor not come at once, in spite of being engaged with any important case, and should he enquire (naturally) whether he will be paid for his time and trouble, he is sure to be censured and condemned by the jury. He must come immediately he is summoned, without expectation of fee or reward; he may not relegate the inquest case to the parish doctor. Such conduct would be considered callous, inhuman and mercenary. When one reads of nearly half the population of a great city being gratuitously treated by us, one cannot blame the public for the aspect in which our calling is thus placed before them. In all other affairs of life, people are accustomed to pay for what they receive, yet all the culture, education, skill and thought of our profession—representing as it

does a considerable money value—must go without remuneration! The reform lies in our own hands and will never come about until and unless *universally* adopted. The only valid objection that can possibly be raised is that in connection with the poor. In this case medical relief resolves itself, into Hospital and Poor Law relief. It lies now with the staff to insist on the supporters of hospitals the fact that their time and labor must be remunerated, funds for which can just as easily be forthcoming as for the dieting, drugs and nursing in the hospitals. In the case of Poor Law relief the pittance now given to parish and district medical officers should be increased commensurate with their laborious and responsible duties.

JOHN MARTIN COATES, M. D.

WHEN troubles come and storms rage high
And quarrels rampant ride,
When the fight twixt helmet and beaver draws nigh.
Who will quell the conflict's tide?
A terrible gloom throughout India's spread
Over North, South, East and West.
For our friend John Martin Coates is dead.
Gone our noblest and our best.

No more shall we hear his welcome voice!
No more see that winsome face!
No more can he teach us, "in sorrow rejoice,
And manfully run life's race."
Though India grieve and the Service mourn,
O'er the radiance once he shed:
His ashes will rest in the clay cold bourne
Till the grave gives up her dead.

Civilians weep for the one we loved,
J. M. Coates who loved us so,
Let us pray that his spirit from realms above
May smile on us here below.
Service and Civil join hands once more,
Remembering all that he said:
Let bickerings cease, they grieve him sore,
His body, *not* soul is dead.

Our sobs us chok'd, not a word was spoke,
But eyes look'd rainy weather;
With that dead who had led us, the last link broke
That kept us joined together.
We moan'd and groan'd as his corpse we laid
In that narrow Indian grave:
Yet from our hearts will he never fade,
Our glorious friend and brave.

Though we'll meet no more in this world of care,
Where our best seems done in vain;
And the cup of joy is clogg'd with despair,
While pleasure is mix'd with pain.
But if we take home his lessons of love,
And follow the path he led,
Perhaps we may meet in the world above,
When the grave gives up her dead.

Doctor Coates our teacher and friend, farewell!
Farewell! rest your body in peace;
But close mistat "your boys" may your spirit dwell,
Your interest never decrease.
Till amity reigns in the place of "fight"
And peace universally spread,
Then we may meet in the realms of light.
When the grave gives up her dead.—R. SETON CHEW.

INSANITARY CALCUTTA.

THE Calcutta Municipality and Health Department have received their *quietus* from the Bengal Government. The letter of the Bengal Chamber of Commerce on Calcutta sanitation and the reply of the Government thereto, are both specimens of masterly activity.

Our columns have repeatedly given evidence of the intense feeling of public indignation in regard to the culpable neglect of the sanitary needs of this city by its Municipal Board. This loud-voiced body has long ceased to command

Indian Medical Association

We do hereby certify that
holding the qualification of
is duly elected a Member of the Indian Medical Association

SUPPLEMENT

TO THE

INDIAN MEDICAL RECORD

OF

1st August 1895

CALCUTTA,
18

SECRETARY

President
Vice-President
Members of Council

either public confidence or respect, and the welfare of the tax-payers seems to have been a matter with them of microscopic importance. The European community is so imperfectly represented in the Municipal Government of Calcutta, that urgently necessary reforms have passed unheeded; while a species of terrorism pervades every department owing to the supremacy of the native vote. The Health Department has been crippled by fear of the native vote, and every official in that body realizes that his bread and butter depends upon the manner in which he steers his craft with this powerful wind. It is comforting therefore to find the supreme arm of the Local Government taking command of an almost reckless and aimless managing body, in the hope that what is urgently needed for the protection of the health of the population of a very large city will be done, and done without delay.

The Bengal Government is to be congratulated, and we feel sure that not only the European community, but every honest Indian rate-payer will sympathise with and support the action of the local authorities.

It is, we believe, due time that the Health Department of the Calcutta Municipality was completely reorganised and a thoroughly practical officer placed at its head.

A MEDICAL TARIFF FIXED BY LAW.

WE quote from the *Lancet*:—"There is a Bill before the Legislative Council of the Cape of Good Hope, a short Bill to amend the Medical and Pharmacy Act of 1891, which provides a tariff of fees for medical practitioners. No practitioner will be entitled to recover any charges exceeding those in the tariff, save in pursuance of any special agreement between the parties."

Schedule Tariff of fees for Medical Practitioners.

Examination of any person and certificate ... £1 1 0
Every visit within the limits of any town or village—

By day ... 0 5 0
By night ... 0 10 0

Every visit outside such limits, besides the charges allowed by the tariff—

If travelling at own cost: per hour ... 0 10 0

If travelling at cost of patient: per hour ... 0 7 6

Any confinement ... 3 0 0

Any certificate of cause of death not involving post-mortem ... 0 10 0

Any surgical operation involving the loss of any limb ... 10 0 0

Any ordinary surgical operation ... 0 10 0

It cannot be said that this tariff errs on the side of excess.

It is very vague. "Any ordinary surgical operation, 10s."

It is very doubtful, too, whether the Legislature is acting wisely in fixing fees. Practitioners who most respect themselves will make their own terms. We shall be curious to know whether such a Bill becomes law.

FACTS ABOUT INDIAN BEER.

A CONTEMPORARY publishes the following statistics of the beer industry in India, brought up to the end of 1894. The first Indian brewery was established at Mussoorie so far back as 1850. Two years later another was opened at Kussowlie; in 1860 the Murree Brewery was founded, and in 1862 a fourth at Simla. Now there are 22 breweries at work, twelve being in the Himalayas; while at Poona, Bangalore, Ootacamund, Quetta, Rawal Pindi, Lucknow, and Mandalay beer is also extensively brewed. The Murree Brewery has the largest output—811,000 gallons being credited to it in 1894, Poona coming next with 793,000 gallons. The total number of gal-

lons brewed last year was 61, 121, 905, the average annual production for the preceding five years having been only 5,285,000 gallons. This shows that the industry is steadily expanding. The troops consume about 55 per cent of the whole amount, the civil population taking the rest. The Government import no beer at all for the army, but some regiments and batteries still get their supplies from England. The quantity imported annually is about 2,850,000 gallons, and this meets the want of soldiers and civilians who prefer beer brewed in Europe. The national beverage is now produced successfully in the plains, though it was long thought that it could not be brewed in a tropical climate. In 1894 over two million gallons were thus brewed, and the quantity is likely to increase. The output has been nearly doubled in the last ten years.

THE CERTIFICATE OF MEMBERSHIP IN THE INDIAN MEDICAL ASSOCIATION.

WE have much pleasure in issuing as a special supplement to our 1st August number, a copy of the Certificate of Membership in the Indian Medical Association.

Art critics have pronounced its design and workmanship as perfectly exquisite. We have a hope that members of the Association will be of a like opinion. The certificate is on parchment and is 14×12 inches in size, above is a replica shewing Hygieia the goddess of health, distributing relief to the halt and the maimed and sufferers of every description, who approach her on either side. Beneath this are two hemispheres, representing severally the maps of Great Britain and Ireland and the Indian Empire; with hands clasping across the hemispheres, supported by a motto scroll, "UNITY IS STRENGTH." The sides consist of oriental pillars of the most delicate structural designs, representing Indian architecture of the most beautiful type. The bodies of the columns are made up of replicas representing well-known medical paintings, such for instance, as JENNER'S first vaccination, VERALDUS lecturing on Anatomy on the dead subject, CHABOT delivering his great clinic on cranial surgery for hystero-epilepsy. The base of the design is made up of a very illustrative sketch of Indian scenery. Surmounting the columns are the emblems of Great Britain and India in the form of a lion and a tiger. The centre of the design is filled in with the certificate form of the Association, with space for the signatures of the Members of Council.

All members who have paid in their subscriptions may now claim their certificates, and they would much oblige if they would kindly forward a post-card request for the same, giving their names and addresses clearly written, to DR. WALLACE, Secretary, Indian Medical Association, 150, Dharamtala Street, Calcutta.

A MEMORIAL TO DR. COATES.

SELDOM has so fitting an occasion arisen, in which the local profession could rightly honor itself in honoring a man who was, every inch of him, A FRIEND OF INDIA. DR. COATES was one of the staunchest friends the local profession has ever had. To allow the memory of such a man to be lost to coming generations of Anglo-Indian and Indian students, would display a melancholy lack of appreciation. A public movement is on foot in Calcutta to raise a suitable memorial to DR. COATES, and we feel sure that hundreds of pupils of the Calcutta Medical College and numerous practitioners throughout Bengal and Upper India will feel it a privilege and a pleasure to take part in the raising of such memorial. We trust therefore that our brethren will need no further entreaty than the bare announcement of the decision and appointment of Treasurer and Committee to deal with funds, as shall be made at the public meeting shortly to be held in Calcutta.

We learn that a similar movement on this behalf has already been made, and that some subscriptions for the purpose have already been collected. We congratulate the promoters, and trust that their action will meet with a large amount of success.

DEATHS BY WILD ANIMALS IN THE CENTRAL PROVINCES OF INDIA.

WHILE fewer human beings were killed by tigers and kindred animals in the Central Provinces in 1894, the number of deaths from snake-bite went up to 1,087 as compared with 1,084 in 1893. Cases of fatal snake-bite were three times as numerous in Bhandara as in the previous year. On the other hand, only 102 human beings were killed by tigers instead of 119. Leopards and panthers accounted for 25 deaths against 30, but only 12 deaths are ascribed to bears compared with the 26 of the previous year. Six children were carried off by wolves in the Saugor District, whereas fourteen innocents were destroyed in the same way in 1893. The mortality among wild beasts was heavier than before, owing largely to the presence of European sportsmen. Two hundred and sixty-one tigers were killed compared with 207; 538 leopards instead of 500, and 154 bears compared with 106. An additional number of wolves, hyenas, jackals and snakes was also despatched. The increase among the cattle slain by these creatures is, however, very alarming. Ten thousand heads are reported to have been killed during 1894 as against 8,000 heads in the year preceding. It is possible that the returns are at fault.

THE INDIAN PRESS ON THE RECENT ILLEGALITIES OF THE CALCUTTA HEALTH DEPARTMENT.

THE *Indian Nation* says:—"It does not appear that the Health Officer's notice addressed to small-pox patients which we considered, has attracted the attention of the Commissioners. There has been in the General Committee no question or motion about it, and no steps seem to have been taken to have the notice withdrawn, or if the Health Officer is prepared to defend it, to have it discussed. We are afraid the *Bangabasi* is right when it says that all the agitation of the 'Babus is to secure their own interests. The Babus know very well that the notice is not likely to be enforced against them, and it is a matter of little consequence to them whether *Domes* and *Chamars* and coolies are banished from their homes or not. Why should they move when they are safe? 'Rights and privileges' mean rights and privileges of the cultured and well-to-do few, not of the people, except upon such a supposition as this, not of course a charitable one, it is difficult to account for the indifference of the Commissioners who sit on the General Committee to a serious invasion of private liberty."

SHOULD PHYSICIANS DEAL COURTEOUSLY WITH ONE ANOTHER?

It appears almost absurd to ask the question, "Should physicians deal honorably and courteously with one another?" but there are so many instances of flagrant unethicallity and discourtesy on the part of the most reputable physicians that *The Medical News* thinks it necessary to submit the question for consideration. Professional courtesy is very often forced and is influenced by one's own professional interest and advantage. Physicians assume to be great respecters of their ethical code in dealing with their superiors whom they are stipitious not to offend, while they trample ethics under foot in their dealings with juniors and those of less repute. Generalists stick to the patients whom they have been requested to advise about, and as our contemporary says, "all the acts of commercial rivalry are regularly used to estab-

lish and hold the market against all rivals." All these infractions of the ethical code are enfeebling the *oppositi de corpore* and are antagonistic to unity, which associations are endeavouring to create in the profession.

AMERICAN OPINION ON THE OPIUM COMMISSION.

We quote from our excellent contemporary the *Pacific Medical Journal*. "In 1893, there was a British Royal Opium Commission appointed to consider the evils of opium-eating and the financial difficulties that would be involved should the traffic be abolished by law. The Commission has reported that it not only found no evil from the 'temperate use of opium in India,' but that in many instances its use is 'even beneficial.' The finding of this Royal Commission reminds us of the findings of a Scotch beadle on the use of alcohol. The elders of a church had reason to suspect that their good old minister was occasionally taking a little too much *uigis beata*. With the characteristic caution of the race, they thought it well to have their suspicions verified by the testimony of the church beadle. They consequently inquired of ANDREW if he had ever seen the good doctor the worse for liquor; ANDREW replied that he had never seen the doctor the worse for liquor, but he had often seen him mickle the better for it."

MEDICAL PRACTICE AND SWEETHEARTING.

THE *Medical Times and Hospital Gazette* is responsible for the following story, which points a moral:—"An Edinburgh graduate, soon after starting practice in a town north of the Tweed, became attached to a young lady residing at the outskirts of the town. For a time he fairly divided his attention between his patients and his sweetheart, but as his love ripened he devoted more time to her, with consequent neglect of his practice. When patients called at his surgery, it often happened that they were unable to see him until they caught him up at the house of the young lady. One night on returning home he found his name-plate had been removed, and great was his sorrow at the loss, until next morning, he found that, undetected, it had been screwed on to the front gate of the young lady's residence. The hint was not thrown away, and, although the course of true love is running just as smoothly, the patients have less cause to complain."

WHAT IS OUR DUTY IN ABORTION CASES?

"WHAT is our duty in abortion cases?" is the question which the censors of the Medical Society of the County of New York have had under consideration. As professed abortionists they have often shifted their crime on to the shoulders of respectable practitioners. Whenever called to a case, it is necessary that the practitioner should act so as to protect himself against the law charging him with complicity in the act. The law demands that all suspicious cases be reported, and so long as the practitioner knows or suspects, or has reason to believe that the cause of abortion was criminal, nothing in professional ethics will save him from the risk of legal punishment if he fail to report the matter. The practitioner however must be very guarded as to how far or in what cases he, in respect to professional obligations, avoids disclosure of the circumstances.

THE DOCTOR WHO DIDN'T KISS.

THE Government of Madras has invited DR. CLARENCE SMITH, on behalf of the Secretary of State, to attend a Commission appointed by him to enquire into his case. The Commission will be composed of one officer with judicial experience and one military officer; the Commission will not take the character of a public or judicial inquiry. DR. SMITH will be allowed to have counsel and the right to

call witnesses, while the Commission will exercise a similar right.

Surgeon-Major SMITH has refused to have anything to do with a hole-and-corner Commission and demands a public enquiry. BRAVO SMITHY!

WANTED! PIOUS DOCTORS FOR MADRAS.

We quote from our ever-amusing contemporary the *Indian Planter's Gazette* :—

"In future when Madras wants a doctor she had better insert an advertisement something like this :

WANTED.

A Well-Bred Young Doctor with no tricks (osulatory or otherwise), must be good-looking, with good manners and paces and absolutely quiet in double harness, and especially quiet in a tum-tum. No Smiths need apply! Prices no object.

Apply with references, P.M.O., Madras.

THE DANGER OF LATIN PRESCRIPTIONS.

THE *New York Times* cites a case in which a baby three months old fell a victim to a Latin prescription. Castor oil was prescribed and written as *Ol. Ricini*. The dispenser used *Ol. Pini* instead and the babe died after two doses of the mixture into which the oil entered as an ingredient. The editor of the *Times* seems to think that the accident preaches the necessity of writing one's prescriptions in the language of the land. It is strange but evidently true that while castor oil would have saved, *Ol. Ricini* killed the child!

SHORT ITEMS.

Assistant Surgeon A Beale, I. M. S.; who is in medical charge of the R. I. M. S. "Clive," sends an interesting account of the Afghan Prince's experiences on the voyage to England. Among the Prince's retinue, there were quite a few ordinary illnesses on the way, and sea-sickness was the prevailing torture.

Healthful circulation, natural waists, broad shoulders, erect carriage, deep breathing sunshine, and open-air exercise give us the vigorous muscles, musical voices, fair faces, rosy cheeks, clear complexions, that brighten homes, lighten hearts, and cheer and bless the world with long and useful lives.

"It should be mentioned, in the interests of antiseptic purity and suffering humanity, that a good stout toothbrush, plenty of water, and some antiseptic dentifrice, applied morning and night, afford a greater safeguard against many diseases than many people are aware."—SIMS WOODHEAD.

There are 4,874 registered dentists in Great Britain, of whom 3,479 practice with no special qualification, but on the strength of their own declaration that they were engaged in the practice of dentistry before the passing of the recent act regulating the profession.

Dr. Allison, L. R. C. F. & S. Edin., whose diplomas were cancelled by the General Medical Council of Great Britain for some professional offence, has been fined £20 for continuing to use these titles.

We announced as the intention of Government to Knight Surgeon-Major Robertson and to give Surgn.-Capt. Whitechurch a V. C. Both these intentions have been carried out while Whitechurch has had his V. C. pinned on him by the Queen.

Professor Henry D. Littlejohn, M.D. of Edinburgh, has had the honor of Knighthood conferred upon him.

The Editor of the *New York Medical Record* says it is the experience of most physicians in this country that over-drinking, except in great moderation, leads to gastric troubles and to gouty, rheumatic and renal disorders.

Says the *Indian Planter's Gazette*:—"On dit Surgeon-Major Clarence Kissington Smith is to be forgiven, and that they only kept him so to speak in, *durance vile, pour encourager les autres!*"

A conference of veterinary officers is to be held at Delhi in October next for the purpose of arranging some common standard of education and plan of examination for Veterinary College students generally.

The following gentlemen from India have obtained the diploma of L. S. A., London:—B. L. Dhingra of Lahore; A. M. St. J. Wright of Madras.

The pain of inoperable cancer has been found by Aikmann to yield in many cases to salicylate of sodium in doses of ten grains three times a day.

Sudden deaths of aged bicyclists from heart disease are beginning to be reported. Aged people and those who are afflicted with heart troubles should not indulge in this exercise.

Mr. Chajoomal, C. M. S. of the Arvi Dispensary, writes of instantaneous relief to the pangs of scorpion bite by the subcutaneous injection of an 8 per cent. solution of muriate of cocaine.

Dr. Zama Feldstein, M.D., has been appointed Manager and Sub-Editor and Dr. J. E. Danenberg Jones, Sub-Editor of the *Indian Medical Record*.

Dr. Atmaram Pandurang has been nominated for election as Dean of the Faculty of Medicine, Bombay, Dr. Macouachie having left for Europe.

The Principal Medical Storekeeper, Madras, will in future be designated the Medical Storekeeper to Government, Madras Command.

The transactions of the Indian Medical Congress are printed and published. They form an ugly ill-bound volume, altogether a disgrace to the printer's art.

Advices to hand state that two more cases of plague occurred in Hong-Kong, and that the disease lingers on in Macao.

We understand that the cause of Dr. Coates' fatal illness is ascribed to his having drunk a glass of milk in the neighbourhood of the Calcutta New Market.

Dr. Barnardo, F. R. C. S., Edin. the well-known philanthropist and redeemer of waifs and strays in London, is to have a public jubilee testimonial on his 60th birth-day.

It is extremely encouraging to find so many Military Assistant Surgeons have enrolled themselves as subscribers to *The Anglo-Indian*. Let all help.

A case of death from eating Cayenne pepper preserves too freely, is reported from Southampton.

Surgeon-Captain J. E. Frank, Medical Staff, has been selected for employment with the Egyptian Army.

Current Medical Literature.

MERCOINE.

Influenza as a Specific Nervous Fever.

It has been pointed out that influenza in many instances appears to fall with severity on the nervous system. After a fairly large experience of the complaint I should be prepared to argue that it is a specific nervous fever. My reasons for calling influenza a specific nervous fever would be:—

1. Like cerebro-spinal fever, it is infectious and accompanied by most of the symptoms and liable to many of the sequelæ of that complaint.
2. The catarrhal symptoms are in most cases trivial.
3. The backache is spinal, and is not affected by posture or ordinary movement in the same way as lumbago. The pain in the limbs ranges from severe neuralgia to mere nerve fatigue or exhaustion.
4. The headache, delirium, tinnitus, etc., are due to implication of the cranial nerves.
5. The vomiting and diarrhoea are probably reflex.
6. The complications are mainly nervous—(a) temporary blindness from optic neuritis; (b) suspension of the senses of smell, taste, and hearing; (c) menorrhagia in females, vasomotor disturbance.

With the most fatal complication—pneumonia—there may be more connection traceable when we know more about pneumonia itself. At present, to bear out my argument, I would only say that pneumonia is a recognised complication of any exhausting disease.

I think we may take it that considering the enormous number attacked the increased mortality from pneumonia is no more than *pro rata*.

The sequelæ are mostly nervous: Insomnia, neuralgias (supraorbital especially), temporary inco-ordination, paresis (from peripheral neuritis), down to simple prickling or numbness in the fingers and toes, loss of memory, impotence, various forms of mental aberration and insanity, and in females, menorrhagia and angioneurosis.

Finally, my contention as to its being a disease of the nervous system seems to be borne out by the treatment most successful up to now. The drugs one hears most about are antipyrin and its allies, bromides, quinine in various forms, and the like, nerve sedatives and nerve tonics. Every fresh epidemic further convinces me that the whole train of symptoms may be traced to the toxic effect of the influenza poison or microbe on the whole nervous system, central and peripheral.—DR. HENRY WAITE in *Brit. Med. Journ.*

Convulsions of Childhood.

DR. CHENBACH, of Bucharest, has recently made a clinical and experimental study of this common complication of early life. Following the earliest experiments of FELTZ and BITTAS, and the more recent ones of BEUCHARD, the author has carried out a series of experimental studies by injecting the urine of epileptic subjects into the circulation of the rabbit. The conclusions which he has arrived at from this portion of the work are as follows: 1. The urine of convulsive affections, filtered and introduced into the circulation of rabbits, produces clonic and tonic convulsive manifestations. 2. These convulsions appear more rapidly, and are more violent than those produced by normal urine. 3. Prolonged boiling diminishes, in part, the toxicity of the urine, and modifies the tussive contained in it. 4. The presence of convulsant substances in the urine of convulsive affections appears to be proven. 5. Bromide of

potassium employed in the treatment of such affections being introduced into animals with the urine containing it, diminishes, or even prevents, such convulsions. 6. In convulsive affections of children the urine shows a more energetic and prompt action than that of adults under the same conditions. In the clinical study especial attention is paid to the convulsions appearing in the course of the infectious diseases. His conclusions are as follows: 1. It is to be admitted as probably the fact that convulsant substances are found in the organism and produce auto-intoxication. 2. Such auto-intoxications give the most satisfactory explanation of the production of convulsive phenomena in children during, or following infectious diseases. 3. Alterations in the liver, by diminishing its antitoxic activity, favor auto-intoxication, and consequently, the appearance of convulsions.—*N. Y. Med. Rec.*

Cardiac Dyspnea.

As the outcome of clinical and experimental observations, ZERNER has found that in voluntary forced respiration there results some loss of respiratory energy in consequence of the increased resistance encountered in the air-passages. In cases of cardiac dyspnea this loss is considerable. That is, the mechanical respiratory quotient, the relation between respiratory activity and the volume of air inspired, is diminished. The characteristic of cardiac dyspnea resides not in increased frequency and deepening of the respiration, but in respiratory insufficiency. This is due to the swelling and rigidity of the lungs, the latter of which acts more especially by interfering with the expansibility of the lungs, so that the amount of air inspired not only is not increased proportionately to the respiratory activity, but under circumstances may be absolutely diminished as compared with the condition present during rest. There is thus a distinction to be made between relative and absolute dyspnea. In cases of cardiac dyspnea, the increased resistance to the passage of air takes part in the reduction of the effects of the respiratory activity. The mechanical respiratory stimuli resulting from deficient oxidation of blood or increased muscular metabolism, and which are present in the blood, cause a deepening and increased frequency of respiration, and may thus affect the results of the respiratory activity by leading to increased resistance in the respiratory passages. The dyspnea resulting from bodily exercise is of cardiac origin, and its degree depends not so much upon the amount of exercise, as upon the functional capacity of the cardiac muscle. The perfection of the effects of the respiratory activity may be considered an index of the functional capacity of the heart.—*Med. News.*

Malarial Pseudo-Tuberculosis.

CHARLES DUBA describes this condition as not infrequent in malarial countries. It attacks persons who for some considerable period have been affected with ague, and begins with marked weakness, depression, loss of appetite, and emaciation. A dry hacking cough, together with dyspnea and irregular temperature, especially towards night, supervenes. Hæmoptysis sometimes occurs. Physical examination shows evidence of apical consolidation. Examination of the sputa, however, does not shew the presence of tubercle bacilli. The cases recover under the influence of quinine and arsenic, provided the cachexia be not too advanced. The explanation of this condition, which may so easily be mistaken for true tuberculosis, seems to be that a local pneumonic process is started at the apices by an accumulation of pigments in the circulating blood. *Brit. Med. Journ.*

Dry Mouth, or Xerostomia.

DR. THOMAS HARRIS reports:—A woman, æt. 30, who had good health until three or four years ago, when the affection began. The mouth was absolutely dry, and there was a

complete arrest of secretion of all the salivary and buccal glands. There was also a decided enlargement of the parotid glands. The woman was anæmic, but all the organs appeared healthy. There was no disease of the pelvic viscera. DR. HARRIS referred to the very few cases of the malady which had been recorded, and especially to two cases recorded by Mr. JONATHAN HUTCHINSON of relapsing parotitis, one of which was associated with a certain amount of dry mouth. DR. HARRIS regarded xerostomia as a functional nervous affection, and thought that, probably, the parotid enlargement had a similar cause, and he referred to Mr. STEPHEN PAGET's communication on the relation of parotitis to injuries and diseases of the abdominal and pelvic viscera.

Brit. Med. Journ.

Transmissibility of Cancer from man to animals.

M. BOINET, after a long series of experiments on the transmissibility of carcinoma from man to animals, states that after having made repeated inoculations on the rat, the rabbit, and the guinea-pig, he concludes that histologic examination of the lesions which resulted does not authorize him to pronounce in favor of such transmission.—*Jour. of Amer. Med. Assoc.*

SURGERY.

The Treatment of Fractures.

DR. F. E. BUNTS in *Medical News* contributes a rather lengthy yet highly instructive article on the above subject. He deprecates that the treatment of fractures has dwindled in importance,—for while the patient may never lie to cavil at an unskillfully performed operation elsewhere, *e. g.*, for strangulated hernia, or a badly managed case of pneumonia or typhoid, a badly-set fracture with its deformity and impaired function of limb is a silent witness of the surgeon's want of skill, not to mention his being charged for mal-practice!

The indications for treatment he treats of under the following headings: (1) Reduce fragments to their proper places; (2) retain them in position; (3) combat inflammation; (4) restore function, (5) relieve pain.

1.—*Reduce fragments.* As to when this should be done, the author recommends that it is best to wait in simple cases until the surrounding parts are more favorable for work, especially should this be done in fractures which open into a joint. All that is necessary is to apply a provisional splint or support at the time of accident. This gives the patient intense relief and admits of his being moved and the fracture to be handled, where there is much swelling and inflammation, so that the outline of the limb is lost and there is much pain, we must remember that all our attempts at reducing the inflammation will be unavailing if we do not give the limb rest. This the author brings about by means of a provisional splint and elevation. These cases, he says, demand chloroform, which enables the surgeon to place the parts in a more favorable position, apply retention splints, elevation and cold applications, &c., to combat the inflammation. The reduction of fragments to their proper places, DR. BUNTS says, looks better in print and in text-books; but it is almost impossible in practice. All that can be done, and which is quite as effectual, is to restore as nearly as possible, the normal outlines of the parts. The usual method of reducing deformity are extension and counter extension, involving much stretching of the parts and intense agony to the patient. Now under chloroform the muscles relax and the operation resolves itself into a simple moulding of the parts. The exact nature of the fracture can also be defined, especially when it enters a joint.

When once properly reduced, the tendency to subsequent displacement of the fragments is very slight. The only danger of an anæsthetic is the tendency to too much manipulation of the parts, because the patient does not feel it. Even though unconscious, every motion of the jagged ends of the bones may lacerate nerves, muscles, arteries, &c.

(2) For the *maintaining of the fragments in position.* An endless variety of splints and supports of a countless number of shapes, curves and angles named after their inventors, flood the market. But the author justly condemns them all and recommends that the simplest splint, or strips of basswood should be employed, *viz.*, having decided on the best position for the limb, use that splint internal or external, anterior or posterior, which best holds the fragments in the desired position. Even fractures involving joints which will not admit of being treated in the extended position are best treated by the simplest and least complicated of angular splints. DR. BUNTS deprecates *fixed dressings*, *e. g.*, those of gypsum, as being productive of pressure-symptoms, and gangrene; splints should be removed and the parts examined and re-adjusted, if necessary, not later than the second day, as when the parts are once set, they do not displace readily, and as repair begins before a week, the exact position desired should be maintained.

(3) *Combating of inflammation.* Extend the limb and, apply cold or heat; cold in the aged and rheumatic may be contraindicated, but ice applied in plethoric cases does great good.

(4) *Relieve pain.* If the fracture is properly adjusted, anodynes are seldom necessary except perhaps on the first day or so,—persistent and excruciating pain is an indication for the prompt removal of dressings and careful revision of splints, padding, bandages and readjustment of the fragments. A very slight change in the dressing gives the patient great relief. The author thinks that if this point were more appreciated and its importance realized, there would be fewer and less frequent administrations of anodynes, and more careful investigation as to the dressings and consequently more carefully adjusted fractures. Serious pain at the seat of fracture after the second day points to a faulty replacement of fragments.

(5) *Restoration of function.* It is not possible to bring about complete restoration, but we should aim at the best possible results. Fixation of joints must be overcome by early massage and passive motion. Injured nerves and compressed and obliterated vessels cause impairment of function in most instances. From 2 to 3 weeks in children and 3 to 4 weeks in adults, is the limit of time for splints to remain on, except in fractures of the forearm, when 6 to 8 weeks is the rule. Compound fractures are not discussed, and as a summary, the author recapitulates all the important points in his article under 13 heads.

Catheterization of the Male Ureters.

CATHETERIZATION of the female ureters is a comparatively simple matter, and has been in vogue for important diagnostic purposes and the treatment of disease of the upper urinary passages for some time, but catheterization of the male ureters is another matter altogether and inseparably difficult, it would seem, until quite recently. BREXNER of Vienna altered the NITZ-LITZ Cystoscope in 1888 by placing a small canula along the undersurface of its posterior aspect. He succeeded once in the female only, but on the whole met with failure, so also FENWICK and HARRISON. In 1893, however, DR. JAMES BROWN of Baltimore published in the *Johns Hopkins Hospital Bulletin* a preliminary report, recording cases of successful catheterization of male ureters with comparative ease, and in some cases even without an anæsthetic, by rigid adherence to

certain details which he mentions—BROWN used BRENNER's modified Nissen-Lawrence cystoscope. He examines the entire bladder with the anterior Cystoscope; this is then removed and the BRENNER Cystoscope with a styllet attached is inserted, a search is made for the ureteral orifice, when found, the styllet is withdrawn and a catheter takes its place right opposite the ureteral orifice and is then gently pushed in. BROWN records three cases illustrative of the diagnostic value of this method of procedure. In cases of tubercular kidney, suppuration or neoplasm, &c., it clears up indubitably, the question of compensatory function, i.e., whether the patient has at least one good kidney which will do the work of the removed one. If this be so, the surgeon can then proceed to excise the diseased one with safety and benefit to the patient. In the course of discussion on DR. BROWN's paper, PROFESSOR WELCH emphasized the great importance of a practical application of this procedure, and related a case where a kidney (moveable) had been sent him for examination. It resembled so much a similar organ of a patient upon whose body the Professor had just performed an autopsy, and who possessed but one kidney, that he, suspected this too was an *only* kidney which had been removed! To the Surgeon's horror, his patient lived 10 days without passing any urine, and died with acute symptoms of *uræmia*! The Surgeon deplored that he had had no *sure* means of ascertaining before operating, whether the patient possessed a second kidney or not.

Is the baby tongue-tied?

DR. CHERVIN, the Director of the Institute for the Treatment of Stammerers at Paris, has made an interesting study of the surgical aspect of this subject. Much performed in certain regions of France, and formerly often done by some of the greatest surgeons, he thinks that its use has a very limited application; for example, in those rare cases where the tongue is bound down to the floor of the mouth by an inferior ankyloglossia, so that the tongue is immobilised. In certain cases where the frenum is too long, and by extending, even to the tip of the tongue, interferes with nursing, then not a mere incision, but an excision is required. This is exceptionally necessary, and though in itself insignificant, it may present serious danger in a little child. It is wrong to think that if an infant nurses badly its frenum must be cut. A little exercise upon the end of one's finger will correct this fault, an operative interference will be unrequired. Cutting the frenum is absolutely useless in correcting defective pronunciation, for this is only to be remedied by a methodical education of the voice by natural and rational exercises—*Gaillard's Méd. Journ.*

To render sponges aseptic.

AFTER many experiments in his laboratory, M. MEILLERE, Director of the Paris Academy of Medicine, gives the following method of rendering sponges aseptic: the shells and stones are first picked out by hand, then the sponges are beaten to remove sand, etc. They are then placed in a 1 to 100 solution of hydrochloric acid for four hours and next washed and immersed in a cold solution of permanganate of potash. Next follows a bath in a solution of sulphurous acid, after which they are washed until all traces of the last acid have disappeared. To preserve until needed, keep them in 5 per cent carbolic acid, 1 to 150 bichloride, or 1 to 300 of thymol solution. To cleanse sponges which have been used once, they are washed in green soap, rinsed in warm water and carried through the treatment mentioned above. It is advisable to submit them to a bacteriologic examination before using again.—*N. W. Med. Journ.*

OBSTETRICS AND GYNECOLOGY.

Present Status of Treatment of Fibroids of the Uterus by Electricity.

DR. A. LAFRÉCHON SMITH, of Montreal, stated that while he thoroughly believes in the operative treatment of fibroids of the uterus, he still saw good in the electrical treatment in certain cases. Electricity is not suitable for every kind of case nor for every kind of doctor, but it is as true to-day as it ever was that for the cure of pain and bleeding, the positive pole of the galvanic current, properly applied, is in the majority of cases effective. The percentage of successes is greatest in those cases in which the fibroid growth is interstitial; it is not quite so great in the sub-mucous variety, although in some cases it has been followed by the expulsion of the tumor from the uterine cavity. The plea for the early treatment of fibroids by electricity is quite as just as that for operative treatment, and even more so. It is entirely devoid of danger, which we cannot say of the operative treatment. One serious objection to the electrical treatment is the length of time it takes to apply it properly. The present status of the electrical treatment is not as good as it should be, because it has been tried by men of insufficient experience and therefore been found wanting. The fact, first mentioned by APOSTOLI, that electricity produces a febrile reaction when the tubes are badly diseased, is of diagnostic value. It is not true, as has been claimed by some, that applications of electricity cause adhesions.

In conclusion, DR. SMITH said that although at present the tide of surgery is in its full flow, the time will yet come when electricity will find an honorable place in the treatment of women who wish to keep their ovaries.—*N. J. Med. Rev.*

Pregnancy and Operations on the Appendages.

DELAGENIERE of Le Mans has performed three operations for diseases of the appendages in pregnant women, and all were afterwards delivered at term. In Case I the patient was three months pregnant, and was seized with symptoms of peritonitis. After the symptoms subsided a tumour was discovered. An operation was performed; an adherent ovarian cyst with twisted pedicle was discovered and removed. In Case III an ovarian dermoid was removed at the fifth month as it had grown very large. In the second case there was disease of the tube and ovary on both sides, and the patient at the fifth month was exhausted from pain. The abdomen was very tender. The appendages adhered to the uterus, and the intestines around them were also adherent. Both tubes and ovaries were removed. There was great trouble during convalescence owing to constipation. The patient was afterwards delivered at term, of a healthy infant. A few hours later she felt severe pain close to the right side of the uterus, and there was nausea with pallor. All the trouble passed away at the end of an hour. A year later the patient was in excellent health. HENRI DELAGENIERE concludes that pregnancy need never modify the indication to operate. It is a complication of the existing disease, rendering operation all the more necessary, if not urgent.—*Brit. Med. Journ.*

Indications for Total Hysterectomy.

DR. AUGUSTUS P. CLARKE, of Cambridge, Mass., regards as the principal indications for a total hysterectomy: Cases in which the uterus may be in a position opposite to that of prolapse, and in such a state of immobility, superinduced by previous inflammatory processes affecting the adnexa, and producing such adhesions of these parts, as to necessitate, for

relief, operative interference. In cases of rapidly growing interstitial fibroids, or large suppurating growths developing from a broad, sessile base. In such cases the operation is indicated not only because of the hemorrhage, but also because of the pressure which may take place upon the surrounding parts, and the destruction it may produce in the vascular tissues in the abdominal and pelvic organs. If a large and rapidly growing fibroid should take on a retrograde process, either spontaneously or otherwise, the morbid growth may afford a culture-chamber into which other disease cells may find their way, and then undergo malignant degeneration. In such a condition, total hysterectomy is the only expedient that will afford a complete and permanent cure. If sarcoma is suspected in any part of the uterine system, it should be an indication for action. Total hysterectomy is absolutely necessary for uncontrollable prolapse, if anterior and posterior colporrhaphy and other plastic operations have been repeatedly tried and have failed to produce permanent relief. It is the only safe and surgical expedient to be adopted in cases of hemorrhagic polypi which present suspicious microscopical appearances after removal. It is called for in ectopic pregnancy; in such cases hemorrhage can be more safely controlled and the patient is enabled to make a more rapid recovery than by the other methods of procedure. It should be undertaken in ovarian disease, in pyosalpinx, and in old inflammation of the appendages. It should be resorted to in all suspicious disease of the adnexa, and in cases of large cysts, as well as in papillomatous developments and otherwise irremovable cysts and intra-ligamentous fibroids and tumours of the broad ligament. *Med. News.*

After-Histories of Removal of Diseased Appendages.

PINESSE has traced 136 out of 268 patients who had been operated upon by LUCAS-CHAMPIONNIERE, both appendages being removed for inflammatory diseases of the tubes and ovaries. The 136 only include after-histories of over one year, the majority being of two years', and a few of five or six years' standing. In only 8 per cent. did abdominal pain persist. It is significant that the pyosalpinx cases gave the best results, the pains felt before operation always ceasing. Persistence of the pain seems to be neurotic. On the other hand, the catamenia persisted in 22 per cent. of the cases, pyosalpinx being the most frequently (50 per cent.) followed by this phenomenon. In the least advanced cases of inflammatory disease subjected to the operation in question, the period ceased in almost every instance. Persistence of the menses is undoubtedly due, as might be expected, to the leaving behind of portions of ovarian tissue. This has been proved in second operations, where corpora lutea were seen on the stump of the old pedicle. In itself, however, partial or occasional irregular menstruation is rather favorable to the health of young patients: The inflamed structures being removed, they can no more give pain and acquire adhesions to viscera, whilst the gradual suppression of the period is less likely to shock the nervous system of a young patient than its total cessation. PINESSE has never seen insanity follow the operation, nor is obesity the rule. All nervous symptoms are to be attributed to the artificial menopause. Vaginismus developed after operation in a few cases, and one patient suffered from contraction of both hands. Both these symptoms seem to be neurotic.—*B. M. J.*

Intractable Galactorrhœa.

VAN TUSSENBROEK describes an unusually bad case in which this troublesome disorder followed an abortion at the fifth month in a primipara. Emaciation set in, and, as no therapeutic measures were of any avail, the mammae were amputated. Microscopic examination did not explain more than might be expected, the glandular tissue being in a very active condition.—*B. M. J.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Composition of Human Milk.

AXEL JOHANNESSEN has made researches on the milk of twenty-five women from 20 to 46 years of age, in the different periods of lactation, from the first to the thirteenth month after delivery. The specimens of milk were taken from both breasts either before or after the child had nursed, under given dietetic conditions, the food being weighed and measured with exactitude. The total quantity of albumin, casein, and globulin averaged 1.104 per cent., varying but little from this figure; the quantity of fatty matters varied from 0.63 to 6.68 per cent., with an average of 8.21 per cent.; sugar, from 2.55 to 9.77 per cent., the average being 4.67 per cent. The specific gravity of milk was in inverse proportion to the quantity of fatty matter; analysis made at different hours of the same day often shewed a notable difference, especially in the fatty constituents, which were much greater immediately after the child had nursed than before, while the quantity of sugar and albumin remained about the same. In the early months of lactation the amount of albumin was greater than later on. The food exercised a great influence on the milk; an abundant diet caused it to be rich in albumin and fatty matters, while a preponderance of amylaceous food made it poor in albumin and sugar, but rich in fatty matters.—*SAJOUS. Univ. Med. Jour.*

The Influence of the Nervous System on Absorption.

LEUBUSCHER and TECKENBURG publish in brief the results of fresh experiments and of new trials of older ones which appeared in detail in Teckenburg's inaugural dissertation, Jena, 1894. These results are as follows:—

1. GOLTZ' opinion, that after destruction of brain and spinal cord the vascular tonicity is increased, so that a frog loses only a few drops of blood from the opened aorta, is insufficient to account for his observation on the loss of blood in the operation.

2. A short time after severing the nerves of one extremity there was seen in that extremity a dilatation of the vessels, slowing of the blood current and, as a consequence, delayed absorption. This disturbance was compensated after a short time.

3 and 4. If coils of empty intestines are exposed and the corresponding nerves in the mesentery are severed, fluid collects within the coils, pale and clear, alkaline, unaffected by heat, and acting in no way upon albumin or starch. The fluid must therefore be a transudation from the blood, not a secretion from the intestinal mucous membrane. Half as much iodide of potash (in solution) is absorbed from the intestinal coil whose nerve supply is cut off, as from a coil of equal length with full nerve connection. In the jejunum more is absorbed than in the ileum.

5. Dogs in whom the large abdominal ganglia were extirpated, shewed after the operation depression, diarrhoea, and later, (despite feeding) an emaciation, which was overcome slowly, seven to eight weeks after the operation. The urine meanwhile shewed an acid reaction, as in starvation of herbivora. Sugar was never found, traces of albumin, often small quantities of blood rarely.—*Med. News.*

The Pathology of the Pancreas.

It is only within comparatively recent years that any notable additions have been made to our knowledge of the pathology of diseases of the pancreas. A decided impetus was given to the subject by the epoch-making researches

of FITZ, who practically established upon a firm clinical basis the symptomatology and diagnosis of acute pancreatitis and allied conditions. Of the etiology of these we practically know nothing, and this line of research affords a field for investigation that promises to yield important and interesting results.

Recent clinical and experimental observations have shown that some lesions of the pancreas are attended with glycosuria, but an even more obscure association is that with the peculiar condition known as fat-necrosis. While this has been observed most commonly in connection with pancreatic disease, it has also been found in some cases in which such disease could not be demonstrated. An interesting contribution to this subject has recently been made by HILDEBRAND who, in a series of experimental observations on cats, succeeded in inducing fat-necrosis by ligation of the pancreas or its vessels, and by transplantation of the organ in whole or in part. In two animals the pancreas alone was ligated; in six others ligatures were also applied to all of the veins. Sugar was found in the urine of one of these. In one instance a bit of pancreas, two by three centimeters, was excised from the continuity of the organ and fixed with a suture in the omentum of another animal; and, again, an entire pancreas was treated in the same way. In another experiment a whole pancreas was scarified and made to surround a portion of the small intestine. The animals withstood the operations well, but in all the characteristic white areas of fat-necrosis appeared in the peritoneum comparable to that observed in man.—*Journ. Amer. Med. Assoc.*

The Microbes of the Eye.

THE researches of bacteriologists have shewn that the conjunctival sac is a famous feeding-ground for microbes of all kinds. A very complete and learned review of the question by Dr. A. CUENOD shews the present status of the subject and indicates that, in time, all inflammatory conditions of the conjunctiva will be distinguished nosologically by their specific microbes rather than by the vascular reactions. Thus he shews that the acute catarrhal inflammations are due sometimes to the bacillus of WEEKS and more rarely to a pneumococcus or streptococcus organism. The purulent conjunctivitis of genital origin is usually due to the gonococcus. Croupous conjunctivitis may be due to the bacillus of LOEFFLER, but is often a mixed infection.

In chronic inflammatory conditions there have been found the trachomacoccus (KOCH, PONCET, MICHEL), the gonococcus, and a microsporon described by Nofsewski. In xerosis, the bacillus of pseudo-diphtheria is present. The bacilli of tuberculosis and of lupus also may develop in the conjunctiva.

According to CUENOD, in the healthy conjunctival sac one never finds the microbes characteristic of the three principal forms of acute conjunctival inflammation (blepharitic, diphtheritic, and contagious catarrhal). Only exceptionally does one meet with staphylococci, streptococci, and pneumococci. The conjunctiva is, therefore, reasonably aseptic in healthy eyes. The constant flow of lachrymal fluid across its surface is believed to have some antiseptic influence.—*N. Y. Med. Rec.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The Transportation of the Dead in America.

THE *Journal of the American Public Health Association* publishes a paper on the innocuous transportation of the dead, by Dr. J. D. GRIFFITH, in which he remarks: "Until

we are educated to the point of the thorough sanitation of cremation, the transportation of dead bodies by railway is, and always will be, a source of danger." This danger, however, we are happy to think, does not threaten our own country in the same degree as it does America, where dead bodies are quite commonly put in baggage cars along with, perhaps, twenty or thirty trunks. It is clear that if the person has died from an infectious disease and the coffin is not hermetically sealed, the luggage may become infected, and by its distribution could prove the cause of wide-spreading mischief. Not only this, but the health of the railway employees is menaced. In 1888 the National Association of General Baggage Agents, including most, if not all, of the main carriers of the United States, adopted a schedule of rules and forms to govern the transportation of corpses, in which it was suggested that a corpse should be wrapped in a sheet saturated with a strong solution of bichloride of mercury and packed in a specified casket. The writer gives it as his opinion that many dangerous maladies have been spread by handling and shipping the dead body, and believes that the whole country must have benefited from these rules, as most of the State boards of health have not only approved, but adopted them with little or no modification. It has been suggested that in all cases where a death occurs from an infectious disease the body should be interred in the same neighbourhood where the death takes place; but, as Dr. GRIFFITH points out, endless trouble might follow with many people who would leave no stone unturned to enable them to remove the body if they so desired. This being so, the only practical suggestion seems to be that a portion of the baggage car should be provided with metal-lined compartments and be used exclusively for the purpose of conveying dead bodies from one place to another. By this means the risk of infection would be considerably minimised, both to the employees of railways and the travellers who entrust their trunks to the care of the railroad companies.—*Lancet.*

Measures for the improvement of Vaccine Lymph.

DR. S. W. ABBOTT says:—In summing up this phase of the subject, I believe that improvement may be made in the production of vaccine lymph in this country by the adoption of the following general and special measures:

1. Cultivation and production of vaccine lymph by the United States Government for the use of the Army, the Navy, and the Marine Hospital Service, and for all public institutions managed by the Government.

Each State to produce its own lymph for the use of its public institutions and for the use of all local boards of health of cities and towns.

2. The abolition of agents and middlemen, and the issuing of lymph directly from the producers to the parties who use it, every package to be stamped with the date of its collection.

3. The employment of better and more uniform methods of inoculating animals.

4. The exclusive use of animals less than one year old.

5. Limiting the time of collecting of lymph to a period of five days, or at the outside to six days from the date of its insertion.

6. The adoption of careful rules for every establishment relative to cleanliness, the care of animals, etc.

7. If adult animals are used, a requirement that they shall be slaughtered before the lymph is issued.—*Boston Med. and Surg. Journ.*

Revaccination and its Effects.

M. HERVIEUX informs us that for the past seven weeks not a single case of small-pox has been reported in Paris. Not since fifteen years ago has such a phenomenon been noted, and this satisfactory condition of affairs contrasts strongly with what obtained about the same time last year. To what may be attributed this happy state of things? M. Hervieux answers unhesitatingly: to the wholesale revaccination practised through the initial aid of Dr. MARTIN, Inspector-General de l'Assainissement. The Academy of Medicine can also claim some credit for its vaccinating department supplied large numbers of tubes and organised extra vaccinating seasons. Such a brilliant result could not, says M. HERVIEUX, have been attained had human, instead of calf lymph been used.—*Lancet*.

Sewage Purification by Polarite.

THE chemical report of M. L. VUAFLEART and the micro-biological report of Dr. BILLET relating to the experiments made at the Exhibition at Boulogne, with Mr. ANDREW HOWATSON'S installation for the treatment of sewage by polarite, are now published. The reports are highly interesting, shewing the experiments to have been carried out with the greatest care, the results being most satisfactory.

M. VUAFLEART arrives at the conclusions that the effluent was at all times limpid and colorless, and that in addition to the organic matter in suspension, from 84 to 88 per cent. of that in solution was removed.

Dr. BILLET'S micro-biological report concludes thus:—

- (1.) Crude sewage 5,250,000 microbes per centimetre cube.
- (2.) Crude sewage after precipitation by Ferozone, 812,500 microbes per centimetre cube.
- (3.) Crude sewage after filtration through polarite, 42,000 microbes per centimetre cube. That is to say a little more than 99 per cent. of the microbes were removed:—*Sanitary Record*.

Barbers and Hair-dressers.

DERMATOLOGISTS and hygienists are agreed that certain diseases are transmitted through the instruments of barbers and hair-dressers. This necessitates the frequent washing and disinfecting of all appliances used by these people, especially before using them again. Carbolic acid will certainly kill the microbes, but its disagreeable odor is hardly the thing in a hair-dressing establishment especially where perfumery is sold. Boiling water is liable to rust the instruments. BLAISE recommends as the best disinfectant to dissolve 10 parts of carbonate of potash or soda in 100 parts of hot water. The instruments come out of this bath in a polished and defatted condition. The essential oils can be utilized; many of them possess well-established bactericidal properties. There are also benzoic acid, thynic acid and creoline, whose antiseptic properties are acknowledged. A sterilizer would be the proper apparatus for all barber shops and hair-dressing parlors.—*Pacific Med. Journ.*

—:O:—

THERAPEUTICS AND PHARMACOLOGY.

The Treatment of Ozena.

MACKENZIE has reported the case of a young lady with a foetid discharge from the nose. The teeth were found sound but it was recognised that ozena was present; large putrid crusts blocked the nares, and when removed were replaced by others. The nose was broadened and the alae were thickened and reddened. In the belief that ozena is a disease of

the mucous membrane, and that the atrophy of sinuses which is characteristic of it is simply due to the pressure of the hardened pus (crusts) upon that membrane, a condition somewhat analogous to that met with in the skin in certain forms of eczema, an attempt was made by excoriation to supplant the diseased membrane by new tissue. After cauterising, oily applications, such as a mixture of ichthyol and olive-oil, were found soothing and beneficial. The treatment was continued during the summer and part of the autumn, and resulted in recovery, which was persistent after four years. Similar treatment has likewise proved successful in several other instances.—*Brit. Med. Journ.*

Splenic Extract in Malarial Cachexia.

Dr. G. COUSIN relates two cases of malaria with considerable swelling of the spleen, that had proved obstinate to the ordinary means of treatment. He then resorted—and successfully—to subcutaneous injections of splenic extract obtained from a fresh sheep's spleen, filtered and sterilized in d'Arsonval's apparatus. He commenced with an injection of 1 gms. (15 min.) of this extract, and gradually increased the dose to 8 to 10 grammes (2 to 2½ fl. dr.). These daily injections often immediately effected an increase in the quantity of urine voided, and sometimes they provoked rather abundant perspiration or a slight rise of temperature, locally, they thrice gave rise to thick, indurated nodules (like hazel-nuts). Their therapeutic effect was promptly manifested, it is stated, by a diminution in the size of the spleen, disappearance of the pain due to the swelling of this organ, recovery of appetite and strength, increase in body weight and in the number of erythrocytes.

After about 35 injections, both patients were considered cured (*La Sen. Méd.*)

Antistreptococci Serum in Puerperal Septicæmia.

JACQUOT communicated to the Société de Biologie the case of a woman attacked by puerperal septicæmia in which intra-uterine injections and quinine were without effect. The symptoms persisted and the evening temperature reached 40.8° C. He then injected 30 c.cm. of ROGER and CHABRIN'S antistreptococci serum. The same evening the temperature fell to 37° C. After three injections of the serum the patient seemed well, when, three days later, her mother contracted facial erysipelas. This seemed to be the origin of a new infection, for in two days the convalescent had a severe rigor and the temperature again rose to 40° C. Only one other injection of the serum, however, was required to arrest the process, and there was no further relapse. JACQUOT remarks that this case, while showing the favourable action of the serum in puerperal septicæmia, and notably on the temperature, further illustrates the reciprocal relationship which exists between this disease and erysipelas.—*B. M. J.*

Cannabis Indica.

MACKENZIE speaks of cannabis in all forms of cephalalgia. He has found it act favorably even in the severe headache attending cerebral growths. In chronic uræmia, where opium is contra-indicated, it is especially serviceable. He has found the remedy to be almost a specific for that continuous form of headache which begins in the morning and lasts all day. In these cases the pain is generally dull and diffuse, but marked by occasional exacerbations. While it is rarely severe enough to interfere with occupation, yet it constitutes a source of constant annoyance to the patient. In such cases the author administers morning and evening from one-twelfth to one-half grain of the extract in pills. If these doses are not sufficient, he

give one grain in the evening and one-half grain in the morning. In very obstinate cases the dose is still further increased, the larger dose always being taken in the evening, until relief is afforded, or toxic symptoms become manifest. In some instances MacKenzie combines gentian, cinchona, or hydnocarpin of caffeine with the cannabis indica. In various neuralgic affections, gastralgia, the pains of tabes the drug often proves very useful.

In skin-diseases associated with intense itching, particularly scutic pruritus, where local applications fail to relieve, cannabis indica is often used with great benefit. The author has rarely observed any untoward effects from its use, nevertheless, to avoid toxic manifestations, the drug should be given at first in small doses, the latter being gradually increased.

Correspondence.

THE "INDIAN MEDICAL RECORD" ON THE OPIUM QUESTION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As one who has sympathized thoroughly with the views always expressed so fearlessly by the *Record* on the Opium Question, and as one who is and has always been in accord with your views, I would congratulate you on the excellent editorial on this subject which appeared in your 16th July number. I have read that article critically and wish to point out some errors in it, which may be due to incorrect type-setting or incorrect copying of figures. I think your article will be greatly strengthened in point and value if you will kindly publish the following corrections. The figures—your figures—are based on the Sanitary Commissioner's Report I presume, and it is from that volume that I am suggesting the corrections to your article.

I trust you will take my intentions in a good spirit, as I feel your hands can only be strengthened by the publication of the following note:—

1. Page 48, 2nd column, 14th line, from bottom the word "opinion" should be *opinions*.
2. Page 49, twelfth line, from para. beginning "Distribution, and prevalence &c.," the word "*habits*" should be *habit*.
3. Page 51, first column, 14th line, from end of para. "the far-fetched" should be "*than far-fetched*."
4. Page 52, sixth line, 1st column, after "a low average," add of consumption: *but the highest malarial mortality in Bengal, as will be seen from the following table.*
5. Omit list of districts after "average" substituting the attached Table I.
6. After list of districts page 52, omit first sentence, from "*In first six districts, &c.*," to "*Moorshedabad*,"—four lines altogether.
7. Correct figures in 22nd line from the bottom, page 52, first column, " $1,106 \times 30 \times 365 \times 12,110 \times 700$ " which should be as follows:— $1,106 \times 30 \times 365 = 12,110,700$.
8. Page 52, 19th line, from bottom of first column, "*11,000*" should be *110,000*.
9. Page 52, first column 19th line, from bottom, the words "*we could not*" should be *we would now*.

10. Page 52, second column, 31st line, from bottom after sentence insert:

11. Page 52, first column, 18th line, from the top for "*Dinajpur and Rajshaye*" substitute *Rajshaye and Jessore*.

12. And in the line which follows—"Show together only 1'38" read—"Show 13'9 and 7'3 respectively."

13. Page 53, first column, 26th line, from bottom the word "lead" should be *lead*.

14. Page 53, first column, 2nd line, below "lead" the word "narcotine" should be *amarcotic*, also the same corrections in 9th line from bottom; and in 2nd and 9th lines from top of second column, page 53.

15. Delete after anarcotine in 9th line.

16. Page 53, 2nd column, 17th line, from top the "or" should be *in*.

Table I showing the annual mortality from malarial fevers; and the average consumption of licit opium per head per annum, in the nine most malarious districts of Bengal:

| Name of District. | Average mortality per annum per 1,000 of population. | Average consumption of licit opium per head per annum. |
|-------------------|------------------------------------------------------|--------------------------------------------------------|
| | | Grains. |
| Rajshaye | 35.48 | 13.8 |
| Jessore | 33.73 | 7.8 |
| Maldah | 33.28 | 33.9 (1) |
| Moorshedabad | 30.85 | 28.5 (2) |
| Dinajpur | 29.41 | 14.4 |
| Jalpalgouri | 29.41 | 6 |
| Naldea | 28.99 | 10.9 |
| Darjeeling | 27.12 | 15.7 |
| Rangpur | 26.11 | 20.6 (20.6) |
| Dacca | 16.81 | 5.1 |
| Maimensing | 16.83 | 5.8 |

(1) In Maldah the excessive consumption is largely due to *madak* smoking, there are 28 shops in the district.

(2) Including the city of Moorshedabad, which raises considerably the average for the whole district.

Yours, &c., D. MORISON,

—:O:—

SNAKE-POISONS AND "ANTIVENENE."

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As much interest is evinced by the public in the vitally interesting question of snake poison, and researches are being made in various parts of the world with the object of discovering an antidote, I venture to offer a few remarks on the subject. On inquiry it will be found that many scientific and experimental truths which modern scientists think they have discovered were not unknown to the ancient sages of India six hundred years before the birth of Christ. The abstract of a paper noticed editorially in your columns on the antidotal properties of the blood serum of animals immunised against snake venom, shews how animals can be protected from snake or other venoms by injecting into them the blood serum of animals that have been made immune against doses of the same or similar venoms. It is further shewn that snake poison is rendered innocuous by being mixed with a weak solution of chloride of gold or hypochloride of lime. That this effect of gold as a curative and a preventive of snake or other poisons was known to the inspired sages of ancient

India is clearly proved by the following translation of *Charaka*, v. v. 186, and 187, c. 25, and *Visha Chikitsahetum Chikitsahasthanam*:—"Finding the patient with symptoms of poison, the learned physician will inquire if he has taken anything particular at any time and immediately cause him to vomit out with copper-powder and honey to clear his stomach. Then he will give the patient a dose of gold-powder (chemically prepared) of half a *tollah*, as it cures poison of all sorts, whether venomous snake poison, metal poison, or poison of herbs; and the poison can no longer remain in the system, just as water cannot stand on lotus leaves." Although the ancients did not bring in to light such a process as injecting the serum of blood of an immunised animal, the fact that they appreciated the efficacy of administering to the patient the blood of venomous snake that had bitten him is clear from verse 191 of the same treatise, which foreshadows in a distant and indirect way the result of Professor FRASER'S experiments, by advising the patient bitten by a snake, or other venomous creature, to bite it immediately and suck its body, the substance so sucked out being applied with saliva to the wound as a means of neutralising the poison. On a reference to the *Bagbhatgita*, c. 38. v. 17, further information on this point may be gathered. That this is undoubtedly a rough way of injection with blood serum may be safely inferred from the texts to which I have referred. Hypochloride of lime may in like manner be compared to *kharaqud* (lime-drug) which, though consisting of several ingredients, contains *khas* (lime) chiefly. (*Charaka*, c. 25., v. v. 35 and 62.) The fact that the deadly poison could be rendered innocuous by inoculating the person bitten with the blood of birds that had been rendered immune was also known to the ancient sages, as will be found in v. 192 of the same chapter, which enjoins that ducks, swans, peacocks, etc., should be reared for the purpose of making them available when required to avert the poison by their contact. The utility of this process has been testified more than once. The *Charaka* deals with numerous ways of treatment and different sorts of medicines for curing snake poison, which may be summarised as follows: (1) The binding process (to stop the circulation); (2) the process of burning and causing blood to flow from the wound; (3) the process of sucking the wound; and (4) the application of medicines (both internal and external). The great treatise also accepts *Sirish* (*Albizzia* *labeles*. Syn. *Acacia labelee* or *Acacia Sirish*) as the best of medicines derived from herbs to avert death from poison. It further affirms that, on the failure of all other medicines, the physician should use metal or vegetable poison in fighting that of the snake, as these have an inverse power of neutralising the deadly effect of each other (*Charaka*, c. 25, v. v. 39 and 12). The *Tantras* also have descriptions of many efficacious medicines for curing snake poison. It is to be hoped that such valuable information as I have cited may be collected together in a compact form and submitted to the ordeal of careful experiment, so that many useful and efficacious antidotes for snake poison may be available to the scientific world.—
Yours, &c.

LALIT KUMAR GUPTA, *Kabiraj*.

CALCUTTA, July 16th 1895.

THE COUNTERSIGNING OF THE MEDICAL CERTIFICATES OF PRIVATE PRACTITIONERS BY GOVERNMENT DOCTORS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Your indignant but just protest against the calumny hurled by a non-descript writer in the lay press, who disgustingly calls himself a member of our profession, was not a bit too soon needed. Evidently the Calcutta public has taken its cue from our sycophantic villifier, and acting upon the supposition that his statement is true, "that with private practitioners the question of medical certificates is simply a matter of fees," a somewhat respectable member of Calcutta society sent me the following insidious letter:—

"Dear Sir,—Excuse me for writing in the strain I am doing, but as the case is an urgent one, I trust you will overlook my presumption and grant the request.

A lady friend of mine is summoned to appear at the Small Cause Court on Monday the 22nd instant, but wishes to have a medical certificate, shewing her inability to attend on the day appointed. Of course, I need not inform you that the lady in question is not indisposed in any way, but leaves the nature of her complaint entirely in your hands.

Should you feel disposed to grant the favor, please let me know your fee for the above certificate.

In any case should you accede, or refuse the request, please say nothing about this letter to any one, although the complainant in the case may try and worm the facts of the case out of you, being a regular patient of yours.

Sincerely hoping you will not refuse, and thanking you in anticipation for the same. An answer, per bearer, will oblige."

CALCUTTA, July 20.

Yours &c., J. A."

To the above epistle I sent the following reply:—

Dear Sir,—I am surprised at your request and assure you most emphatically that I do not believe that any physician could but feel offended at such a letter, for you simply ask a doctor to certify to a falsehood and offer him a fee for doing so."

As I send you the original letter sent by the applicant, who could easily have been prosecuted under the Penal Code, I trust it will be clear to the detractors of the local profession that we are not guilty of the faults and misdemeanors which such cringing perversers of the truth as *Medico* would have the lay public believe.

Yours &c., L.R.C.P. & S. (Edin.)

REVIEW.

LEPROSY: in its clinical and pathological aspects. By DR. G. ARMAUER HANSEN, Inspector-General of Leprosy in Norway, and DR. CARL LOOFT, Assistant Physician to the Lunge-gaards Hospital. Translated by NORMAN WALKER, M.D., F.R.C.P., Edin., Assistant Physician for Dermatology, Edinburgh Royal Infirmary. With numerous photographs and colored plates. Bristol: JOHN WRIGHT & Co., Pp. 162. Price 10 s 6 d net.

This splendid monograph on leprosy from the pen of two of the most experienced experts in dermatology will, to a certainty, be welcomed by the profession, for while *acanthosis scrophulæ* prevails to a very large extent, it is true, still the treatise before us is not in any wise a redundancy in the matter of works on leprosy. The

authors say. "We hope to be able to lay before experts a thorough, complete, and instructive demonstration, the more as we do not base our views, as has been frequently and unfortunately done, on any single or scattered observations." This desire is most thoroughly and faithfully carried out in their conjoint work on leprosy. The translator, DR. NORMAN WALKER, has completed his task with assiduity, carefulness and absolute accuracy. There are of course, many points on which there is much divergence of opinion. For example HANSEN's view of the position of the bacilli in the cells, which is extensively held, is strongly opposed by UNNA &c.

The chapter on treatment has been wholly re-written for this edition, and is a résumé of DANIELSSON's views. In this connection we may venture to remark that any new drug or method of cure, which, after a fairly extended trial, could be pronounced efficacious, even temporarily, would be hailed with a joyous welcome. With this end in view, we made a scrutinizing search among the pages of the erudite treatise before us to see if it could shed any ray of hope, or recommend any medication or method of treating this fell disease other than those already in vogue—but in vain—Of the 25 remedies enumerated, that have been tried, with more or less success in the hands of some physicians, *not a single one* can be relied upon. *Re* the curability of leprosy during its incipient stage, the authors say: "we have seen cases of leprosy, in the country (Norway), both tuberculous and maculo-anæsthetic, completely recover *without any treatment whatever*." The only alternative is *prevention* by means of segregation and isolation in properly constructed asylums. This has been the means of reducing the number of lepers in Norway from 1833 cases in 1856 to 950 cases at the end of 1890.

Regarding the inoculability of leprosy to lower animals, the authors remark, "unfortunately, all attempts to inoculate animals *have failed*."

Referring to "*The Recrudescence of Leprosy, and its Causation*," by WILLIAM TERR, the authors likewise consider that distinct proofs of Mr. TERR's contention that leprosy may be conveyed by vaccination from arm to arm are wanting.

No reference is made to the recent Indian Leprosy Commission, as DR. HANSEN has published his views thereon in the *Lancet* of October, 1893.

The work is divided into 8 chapters, which are devoted to a description of the two forms of Leprosy, the structure of the Leproma, Pathology, Diagnosis, Prognosis, Etiology and Treatment of the disease. There are 4 "Plates," or *photo-tints* illustrating patients suffering from the two forms of leprosy, and at the end of the work, 8 beautifully tinted chromo-lithographs of pathological microscopic specimens shewing lepra bacilli and globi.

Altogether the work is a compendium of the most recent research and investigation into the nature and treatment of that very scourge of diseases—Leprosy. The authors have brought together the latest advances made by Scientists in the consideration of this disease as treated in the Langesgaards Hospital in Norway, which will be of great value to the busy practitioner and the aspiring student. The letter-press is easily and comfortably readable, thanks to the publishers, Messrs. John Wright & Co., of Bristol.

Government Medical Gazette.

GOVERNMENT OF INDIA.

The services of Surgn.-Capt. H. B. Melville, M.B., C.M., I.M.S., (Bengal), are replaced temply. at disposal of Mily. Dept.

QUININE IN CHOLERA.

By SURGEON-CAPTAIN PATRICK HENRI M.D.,

F.R.S.E., F.R.C.S.E., D.P.H. (Cantab.)

Lecturer on Pathology and Clinical Medicine, His Highness the Nizam's Medical School, Hyderabad.

A RECENT issue of the *Indian Medical Record* alludes to a statement by an American writer to the effect that the use of quinine in the treatment of cholera should reduce the mortality by 6 per cent. Whilst I am an ardent advocate for the use of quinine, both prophylactically and therapeutically in cholera, and have used it for four years in this way, I doubt whether we can ever approach such a low mortality by the use of quinine, except at towards the end of epidemics. I believe I was the first to show that the use of quinine in cholera is a perfectly rational line of treatment, and although my reasons for so employing it may not be accepted, the results obtained indicate that it is at least deserving of further trial.

We have recently passed through a terribly severe, though localised, epidemic of cholera, from the commencement to the end of which quinine formed the fundamental agent used in the treatment. It was administered in every possible way that could ensure a certain quantity getting into the system within a limited time. We gave it as a rectal injection (in the same way we use it in amœbic dysentery), by the mouth, and hypodermically. The particulars of the way of employing the drug are given in a paper that will be published shortly. The statistical results are not so encouraging as the writer quoted would lead us to believe they should be, but as more than half (55 per cent.) of the cases were only brought under treatment during the stage of collapse, it is scarcely fair to judge of this particular group of cases recorded in that epidemic. Of the 88 treated during the first stage with quinine, 58 recovered or about 67 per cent; but of the 103 cases treated in the collapse stage, only 50 recovered, or about 48.5 per cent. Prophylactically we have given quinine for the last four years also, and although we cannot adduce large figures to show its effects in this direction, yet *pro tanto* they are satisfactory, for in no instance did cholera occur in persons who at the time of attack were taking large doses of quinine. In the early epidemics of cholera during my incumbency as Health Officer of the Cluddergaunt Municipality (1887-1890) we lost several members of our sanitary staff yearly from cholera—almost always men who were engaged in carrying out the treatment of pauper patients, or in fumigating or disinfecting houses, or in destroying the defects, or were in other ways brought into close relation with the infected. In one epidemic we lost 7 out of 51 sanitary peons, and 6 out of 74 sweepers from cholera. Since then we have only lost four men, and we attribute the difference to the use of quinine by many of those employed. The theory upon which we use it is, that in cholera there is a hæmatozoon in which sporulation is continuous, and not intermittent, as is the case with the *plasmodium malarie* of ague. It is now well

known that in ague, once sporulation has begun, quinine has no effect on the process, but if it be given a few hours before sporulation commences, it checks the process;—hence the frequency with which we see a 30-grain dose of quinine check an ague, when given four hours or so before the regular attack, although it may have been given regularly in divided doses for several days previously without any effect. I also believe, although the evidence to that effect is not quite complete, that it is during sporulation the poison which causes ague is manufactured, this poison producing a profound effect on the sympathetic system, besides disturbing the thermotoxic mechanism. If we can prevent sporulation, we check any further creation of the specific ague-producing virus. I believe that similar principles should guide us in our treatment of cholera, although in it sporulation has already occurred and continues until we intervene to prevent it with the appropriate remedy. This being so, there is already a quantity of the virus in the system. Having effected the cessation of sporulation, our every effort should be to endeavour to effect the elimination of the toxins which have such a paralyzing effect on the vital functions. It is very probable that Sir GEORGE JOHNSON was not remote from the truth when he stated that the alimentary tract was one of the outlets for the poison. In the stage of collapse the system cannot tolerate any further loss of liquid with advantage, and as absorption is for the time being paralysed, there being an exosmosis instead of an osmosis, we should endeavour to replenish the blood by a saline fluid (such as SCHMIDT'S) in some way.

There are two chief means of effecting this: through the peritoneal cavity, as originally suggested by Sir B. W. RICHARDSON, or through the veins. My experience of the former is nil, but I have done 15 transfusions, and I consider that in the treatment of cholera in the stage of collapse, the continued use of quinine, and the introduction of saline fluids into the circulation is capable of effecting a great reduction of the mortality. I see no reason why the soluble form of quinine should not be introduced at the same time, as we introduce the saline fluids in imitation of the treatment followed by MARCHIAFAVA, BIGGAMI, and others in the treatment of the pernicious malarial, or summer-autumn fever of Italy.

A TYPICAL EPIDEMIC OF CHOLERA.

By D. MORISON, M.D., C.M.

Rajshaye.

ABOUT the middle of October, an annual *mela* is held in the district of Rajshaye, at a place called "Ketre," 12 miles distant from Rampore Bauleah. Every year as the *mela* ends cholera breaks out either in the *mela* itself, or along the course taken by the pilgrims on their way to their homes. Some years so-called sporadic cases occur within the municipality of Rampore Bauleah; at other times it assumes the form of an epidemic. I have observed these visitations for many years, and in every epidemic found good reason for believing that the water-supply at the river ghats, or in the numerous tanks, was contaminated by cholera defects. This year having traced one of these

miniature epidemics, which occurred shortly after the main, to its source. I thought it might be of interest, and worthy of record as a typical epidemic of cholera.

On the 25th October last a man came to the Mission Dispensary for cholera medicine for two patients who were ill in a village called Bindatampore, about three miles from my dispensary. He stated that four persons had already died, and that two others were ill; but that the first case—a woman who had been to *Ketre mela*—had recovered. I did not find it possible to visit the village till some days after, but meantime ordered them to close the well in the court-yard of the house where the first cholera case occurred. I had learned from the messenger that the woman who had been to *Ketre mela* defecated near the well from which the family and others obtained their drinking water. The order to close the well was not complied with, until some more fresh cases occurred, after which the well was abandoned. After a few days I visited the village, got as many of the people together as I could, and asked them particularly regarding the water-supply of each house in which a case of cholera happened. I found that every house, without exception in which cholera had appeared, took their drinking water from the well in the court-yard of house number No. 1. I also examined the place on the verandah, where case No. 1 slept, and the place where she latterly defecated. It was exactly 7 feet 6 inches from the well. The well itself is what is called a *kutcha* well. It is lined with burnt clay rings to keep it from falling in: its diameter is 22 inches, and the surface of the well-water was 2 feet 6 inches from the ground level. During the illness of the first case, the unseasonable heavy rains which fell towards the end of October, occurred. Thus, the conditions for the actual contamination of the well-water with cholera dejecta could scarcely be more favorable, unless they were dropped into the well. The results of the epidemic—12 cases and 10 deaths—prove, I think, that infection of the well-water must have taken place, either through soakage and filtering down of the surface water containing the virus, during and after the heavy rain; or possibly by the woman herself, in the act of drawing water from the well, with her hands (the left hand is invariably brought into actual contact with the faeces in the process of ablution after defecation), conveying the virus to the rope or vessel with which the water is lifted.

The following table shows the results of the epidemic in the village:—

| | | | |
|----------------|-------------|-----------------|--------------------|
| House No. 1 .. | 1st case .. | A woman | aged 55 recovered. |
| | 2nd .. | A man | " 40 died. |
| | 3rd .. | A woman | " 35 " |
| | 4th .. | A man | " 25 " |
| House No. 2 .. | 5th .. | A woman | " 35 " |
| | 6th .. | A woman | " 30 " |
| House No. 3 .. | 7th .. | A woman | " 40 " |
| House No. 4 .. | 8th .. | A boy | " 15 " |
| House No. 5 .. | 9th .. | A woman | " 35 " |
| House No. 6 .. | 10th .. | A child, female | " 3 " |
| House No. 7 .. | 11th .. | A woman | " 60 " |
| House No. 8 .. | 12th .. | A man | " 30 " recovered. |

These were all the cases that occurred during the epidemic in the village, and all these households took their drinking water-supply from the well in the court-yard of house No. 1. There was one house, much nearer the infected house than some of the houses attacked, in which no case of cholera occurred; but the man himself gave the explanation, by informing me that he had a well of his

own, and did not deign to go to the well of house No. 1 for water. Thus he had at least one source of water free from the illness of the first case.

There are some points of great interest and importance connected with this epidemic to which I wish to draw attention: (1) facts like these, and they are common in Bengal every year, should make one hesitate to state publicly, as Dr. Duka did at the 8th International Congress of Hygiene and Demography, that "attacks of cholera occur in numerous villages at a distance, which do not use (contaminated) river water at all. How did these wells and separate and independent sources of water-supply get their *comma bacilli*?"

The answer is given by the facts connected with the origin and spread of this epidemic; and I believe a similar answer could be given in every such supposed sporadic case if we could only trace as easily, the different ways by which the virus or bacillus is conveyed to the alimentary canal.

Another illustration of the same point was afforded a fortnight later by a case of cholera which happened in a village named Bhirmeriang, one mile-and-a-half north-west of Bindatampore. It looked uncommonly like genuine "sporadic cholera," for I could trace no direct connection between the villages during or after the first epidemic. The infection could not be carried by the wind, as the prevailing wind was north-west. I enquired where the boy had been before he took ill, and learned that on the 14th November he had accompanied his uncle on a cart to Rampore Bauleah, five miles distant, where cholera cases were occurring almost daily. He remained there that night, took food and returned on the following day, 15th November, on the evening of which day he was seized with cholera, but eventually recovered. Then his grandfather, two brothers and a little girl took ill and died, four deaths in all, confined to one house. Another case was said to have occurred in the next house, but the woman recovered. Outside of these two houses no cases of cholera occurred in the village. The epidemic ceased entirely. I again made minute enquiries a week or ten days after, but no other person outside these two families took cholera. All the other villagers were independent of that house; each house had its own well, and hence the epidemic was limited to those who came into direct contact with the boy who brought the disease to the village. A little careful enquiry was sufficient to elicit information that entirely dispelled the "sporadic theory."

(2) DR. DUKA further says: "And when the disease attributable to the presence of these micro-organisms in well-water ceases, what becomes of the enormous crop of these microbes, or why does the bacillus so suddenly lose its pathogenic properties to become innocuous?" It is a question that naturally occurs to any one who has given attention to the disease. We have long been familiar with the undoubted fact that in all great epidemics of cholera there is a brief period—very brief in most epidemics—during which the virus has not seemingly attained its maximum virulence. A second period, longer in duration, of intense virulence, and a third period at the close, when it is on the wane and about to become mild or even innocuous. The epidemic before us illustrates these periods.

the first reserved, the last, however, recovered, the last man attacked is a young man, but all the others died. The same is not verifiable in the second epidemic at Bhirmerdeng. The first recovered, so did the last, all the others attacked died. Although we may not be in a position to give a complete answer to this question, or be able to explain the process by which the comma bacilli lose their pathogenic properties, yet the fact itself may be placed beyond doubt and become available for practical purposes. That the virus of cholera does lose its pathogenic properties or become inert in water after a time, has long been known; and the fact is once more emphasised in this epidemic—for the villagers began again to use the same well-water 14 days after the last case occurred, but no recurrence of cholera took place. KOCH^o whose investigations supply us with the most reliable information regarding the life history of the comma bacilli, informs us (1) that the period of activity and growth of this micro-organism, in suitable media, is brief but extraordinarily rapid up to a certain point, then they begin to decline, and their growth is arrested, but after two or three days they shrivel up and die, or become a prey to other bacteria present in the media; (2) that in the tank-water at Calcutta, where the soiled linen of cholera patients had been washed, the bacilli at the height of the epidemic "were so abundant that their number could not have depended on the dejections and washing water† from the cholera linen thrown at one time or another into the tank. Some growth must have taken place;" ‡ that the comma bacilli, although anaerobic, maintaining vitality without air or oxygen, yet require air or oxygen for their activity and growth.

If, now, we compare these characteristics of the comma bacilli with the behaviour of the infective material of cholera, we are at once struck with the correspondence between the alleged cause and the result as observed in epidemics and individual cases of cholera. Let me repeat them briefly: (1) the comma bacilli develop with extraordinary rapidity in suitable media, and subside in two or three days; so do the symptoms produced by the virus of cholera; (2) the bacilli die or become inert in water after three or four days, so does the virus of cholera; (3) the infective material of cholera, when it finds its way into well-water, must remain on or near the surface, as only the surface water can be lifted for drinking or culinary purposes. This also accords with what we know of the comma bacilli; they come to the surface to obtain from the air oxygen necessary for their growth and development. That the bacilli after becoming inert should again become virulent on passing through the alimentary canal of the human subject is to be expected from what we know of other infecting material. Thus the virus of rabies, the virulence of which has been diminished by passing through from monkey to monkey, may again be made intensely virulent by passing it through from rabbit to rabbit or guinea-pig to guinea-pig.

I do not say that these facts answer the question how the virus of cholera becomes inert; but I do say that

indications are not wanting in these investigations that the present trend of scientific research is in the right direction.

It will readily occur to one familiar with the above facts that the cause of an epidemic of cholera tracked as a sheet of water contracted into a superficial area, of less than four square feet (that being the area of the surface of the well), presented a unique opportunity for finding the microbes outside the human body, completing the missing link and thus proving beyond doubt that the comma bacilli are the cause of cholera. This occurred to me at once, and I further thought that, if it could be contracted into a surface of 22 square inches, why not still further contract it to less than half a square inch? This I attempted to do by taking a clean glass-stoppered bottle, full of the surface water of the infected well, during the height of the epidemic, and letting it stand for 24 hours or longer to allow the microbes time to come to the surface in contact with the air. The glass-stopper was removed, a glass cap admitting air freely, but excluding dust, was fitted on and the bottle set aside for examination. I had now, I thought, cholera microbes concentrated in a layer of water less than half a square inch, and ready at will to be put on the slide, or cover glass of the microscope for examination. I examined one drop after another without definite result, and concluded to abandon the search, as handling the water was not without risk to myself and others at that time.

The contents of the bottle were thrown away. Again I relented and sent for other two bottles of the water; but the epidemic had subsided, and it was doubtful whether the microbes could be there at all. I examined carefully and at last was rewarded by the sight of a field of microbes answering, I thought, in every respect to the comma bacilli described and delineated by KOCH.

I am, however, so convinced that the field was genuine that I shall not abandon the search, but apply the method adopted to the first suitable contaminated well I can obtain. The method is simple, and I think, efficient for those who, like myself, may have neither time, talent nor apparatus for conducting investigations with pure cultures of the comma bacilli.

The impression left on my mind by this miniature epidemic of cholera at Bindarainpore is not that it has taught us anything which we did not know before, but that it reiterates and emphasises the outstanding facts already known to us, viz. (1) that cholera does not arise *de novo*; (2) that it is due to an infecting material contained in the cholera dejecta, (I believe the comma bacilli) which can be conveyed to the alimentary canal by drinking water or other moist media; (3) that the virus loses its pathogenic properties after a time in well-water; (4) that its virulence is intensified by passing through the human subject; (5) that those who come most into contact with infected water suffer most, i.e., the women in the Indian villages. Since the above was written, I found that cholera was prevalent in two other villages. I investigated these epidemics to see if they would bear out the conclusions at which I had arrived. The following facts were elicited: (6) that looking to atmospheric conditions, rainfall and subsoil water, conditions which may and do modify epidemics—for the cause of cholera—is only diverting us from the true cause of cholera, which will invariably be

^o Dr. Robert Koch's Contribution to Cholera, Berlin, July 1904.

† The people of Bengal always wash their clothes in the tank, or if by a stream, it is done in the same way as in Europe is done, the water of which is thrown away.

found to be connected with infected ingesta in some liquid or moist form.

Additional facts regarding Epidemics of Cholera at the villages of Koola Tickor and Goshaitpore.

I. The first case of cholera which appeared at Koola Tickor was a woman who took ill on the 19th October 1894. The soiled clothes of this case were washed in the village tank in which all the villagers wash their clothes and bathe. This tank also supplies the village with drinking water. The tank is about 50 yards square and lies north and south, thus:—N. E. the north end being nearest the village. The clothes soiled with cholera dejecta were washed at the north-west corner of the tank, and all the 28 cases of cholera which occurred in the village up to the 15th December 1894 bathed at and obtained their drinking water from that corner of the tank. Those who bathed and used the water at the north-east corner of the tank were free from cholera. The epidemic went on continuously for seven weeks. On the 15th December I visited the village and found the epidemic as severe as it had been at any time during the previous seven weeks, and it gave no indications of abating, six persons being ill on that date. I was informed that at the end of the first fortnight there were indications that the epidemic was abating, but immediately afterwards it began again as severe as before. I explained to the assembled villagers the sources and media of contagion, and urged them either to abandon the tank altogether for a time, or to boil all the water taken from the tank before using it.

There were 28 cases of cholera up to the 15th December, and after that date up to the present time, no new case had occurred. They rigidly adhered to the instructions given, and the result was as stated. The epidemic which had gone on for seven weeks ceased entirely. The 28 cases consisted of 13 women, 10 children under 6 years of age, 3 children over 6 and under 12 years and 2 men. It may be asked why in this epidemic did the virus continue so persistent, since it was proved that the virus in the well-water epidemic at Bindarampore became inert in the course of 14 days of its own accord? The answer is given by the ascertained fact that the soiled clothes from each cholera patient were washed in the tank, and thus as the first infection disappeared, it was replaced by a new infection of the tank-water through the soiled clothes from fresh cholera cases.

II. While this epidemic was at its height, a man and two children fled from Koola Tickor on the morning of the 1st December to Goshaitpore, a village one mile distant where cholera had not yet appeared. At noon of the same day one of those children, a boy 8 years of age, was seized with cholera. He remained that day and all night in a house, 10 yards distant from the village tank. On the following morning the villagers sent them back to Koola Tickor, but not before they had contaminated or infected the village tank. In 9 days there were 10 deaths in this small village. I visited the village on the 10th December, and told them not to use the infected tank water, unless previously boiled, and endeavoured to explain to them the sources and media of contagion. They abandoned the tank and the epidemic ceased, no new cases having occurred after that date. In this village also the heaviest mortality fell on the women. There were 10 deaths, consisting of 7 women, 2 children and 1 man.

MALARIAL FEVERS AND CARBOLIC ACID TREATMENT.

By Asst. Surgeon, C. A. NARAYANA, L.M.S.

Kadur Medical Union, Chikmagalur.

Seeing that no cases of malarial fever, specially those accompanied with typhoid symptoms, treated by carbolic acid have been reported in your journal, I take the opportunity of bringing to the notice of the profession a series of cases that were so treated by me successfully in my private and hospital practice.

First case.—A Eurasian lad, *et.* nine years. The parents of the little patient having tried various patent remedies for six days without any good result, I was sent for.

Examination.—The skin was quite hot with a temperature of 104° F. The patient was in a delirious state, not having slept for two nights, and had a dry typhoid tongue, with puffiness and tenderness over the abdomen. The bowels were loose, moving about four to six times during the 24 hours, but were not quite characteristic of typhoid motions.

Treatment.—The usual antipyrine treatment, with cold baths, was tried for two days, without progressing at all, and the temperature not reducing, the symptoms became alarming and made the parents and the medical attendant anxious. I put the patient on the following mixture:—

| | | | |
|---|---------------------|-----|--------|
| R | Carbolic Acid, pur. | ... | ℥xxxvi |
| | Spt. Chloroform | ... | ℥ii |
| | Tr. Cardamom. Co. | ... | ℥iii |
| | Syrup of Roses | ... | ℥ii |
| | Aquam Camphor ad. | ... | ℥xii |

Sig.—Half an ounce every second hour with an equal quantity of cold water.

Five doses of the above mixture were taken from 8 A. M. to 8 P. M.

Result.—The patient, after five doses, perspired freely. He had two hours' sleep in the afternoon—the temperature went down to 100° for the first time. Tympanitis and the number of motions decreased, and he had a good night's rest. The mixture was now stopped, thinking that the temperature would not go up, but the next day towards morning, the patient began to develop the old symptoms, and the temperature mounted up to 103°. The patient was put back on the carbolic mixture, whereupon the symptoms at once decreased, and the temperature went down to 100°. From this time the carbolic acid mixture was kept up three times a day, steadily, with the result that the temperature never went up above 101° F. The fever subsided on the 25th day without any alarming symptoms throughout. The patient progressing, was put on quinine and arsenic as a tonic twice a day after food.

CASE II. A Mahomedan lad, *et.* 8 years had the same symptoms as the case above cited, but of a less serious type. The carbolic treatment proved successful, the antipyretic one failing.

CASES III-IV. were a Eurasian and Mahomedan lady respectively, who both suffered from remittent fever for 14 days. The same treatment was successfully adopted in both the cases.

CASE V.—A Mahomedan boy of 12 years was brought in from a village about 2½ miles away, having suffered

from food and exposure of bowels for over 15 days. After trying all the alkaline drugs the case was sent to me for treatment.

Examination: At first the patient presented signs of typhoid fever, but on closer observation I diagnosed it as a case of typho-malarial fever; as usual the antipyretic treatment failed to improve the graver symptoms and the ignorant parents began to grow tired of the carbolic treatment after a couple of days only.

On the 18th day, I put the boy on the carbolic mixture giving only four doses within 12 hours. To my surprise and to the joy of the parents, the boy improved steadily.

Diet.—In all the cases, the patients were given plenty of cold water to drink. Soda water was given freely and a strict milk diet with Mellin's food and essence of chicken.

Remarks.—No stimulants of any kind were found necessary. When the cases were put on the mixture the tongue cleared and lost its typhoid condition, the skin was cooler and moister and the patients never shewed any signs of weakness or prostration, which is generally the after-effect of continuous high fever; they were more cheerful than usual, and convalescence set in sooner in all the cases I observed. In a few other cases the usual long course of fever was to a greater extent checked.

The objects for quoting the above cases in your journal are:—

First.—Not having read in books or journals, of such cases being treated by purely carbolic acid, though it has been recommended by many physicians for typhoid fever.

Second.—The treatment has also acted well in cases of purely malarial fever (remittent fevers).

Third.—To request the members of the profession, who meet with such cases, especially those in malarial districts, to give the treatment a fair trial and to report successes in your valuable journal.

Fourth.—The success with which these cases have come out, where the ordinary routine antipyretic treatment would have failed and caused a deal of dissatisfaction and unpleasantness.

Fifth.—Large doses of carbolic acid being borne by the patients without any bad results.

Sixth.—I am inclined to think that large doses of carbolic acid prevent, in a way, the propagation of the malarial poison already in the system, thereby keeping down the fever and acting decidedly sooner and safer than quinine, which is advised to be given in the early stages to destroy the merozoites of LAVERAN.

ON SOME MODIFICATIONS IN THE USUAL METHOD OF EXTRACTING SENILE CATARACT.

By DR. B. H. NARAYATTY, L.M.S.

Teacher of Surgery and Midwifery, B. J. Medical School, Ahmedabad.

HAVING had many opportunities of performing the different operations for the removal of "senile cataract" I now beg to lay before the profession a few slight modifications in the usual method, which time and experience have suggested to me.

Without entering into the details of the different operations or the methods which surgeons from time to time have practised, it will be enough for me to mention that for a long time past it was the practice of ophthalmic surgeons—as indeed it was with me also—to remove the cataract by the "Modified Peripheral Linear Extraction" method (Graefe's operation), with the usual recognised stages of (1) external incision; (2) incision; (3) laceration of the capsule; (4) extraction of the lens; (5) cleaning the pupil of any cortical masses which may have been left behind, and the adaptation of the wound.

The incision in the eye was made just outside the micro-corneal junction, and it was rightly supposed that the peripheral position of the incision—lying as it did in the plane of the crystalline lens—enabled the cataract to be delivered without rotation on its axis. It was however, noticed that these little advantages, due to the position and form of the incision, were greatly counterbalanced by certain other disadvantages, as the escape of vitreous and the difficulty of preventing the iris from being entangled between the lips of the wound.

Owing to these facts, this operation, I believe, has now been practically abandoned by surgeons, who generally prefer to extract the cataract by the 3-millimetre flap operation first brought to the notice of the profession by DR. WEEKER.

It is, I believe, the usual practice with ophthalmic surgeons—and it is the one enjoined in most of the text-books—to freely dilate the pupil by atropine previous to the operation. For many years I invariably followed this rule, but have recently given it up in favor of eserine, and the results that I have thereby obtained have been so favorable, that I now generally prefer to contract the pupil (by eserine) in the following manner, as advocated by SWANZY and others:—

A short time previous to the operation a few drops of a 2 p.c. solution of sulphate of eserine (made with 1 in 5,000 of mercuric perchloride solution) are dropped into the eye, whereby the pupil is contracted to a pin's point. Of course the conjunctival sac and the face are well washed with boracic acid lotion or perchloride of mercury lotion (1 in 10,000) and the required instruments sterilised by being carefully boiled, whilst the eye is rendered anæsthetic by instillations of hydrochlorate of cocaine (4 p.c.). It is unnecessary for me to enter into a minute description of the 3-millimetre flap operation, which will be found in all the recent text-books on the subject. It will only be sufficient for me to point out the slight modification which I have adopted for some years past (having heard that some surgeons did the same by combining the 1st and the 3rd stages into one). It is usual with me now-a-days to lacerate the capsule with the point of the knife, at the same time that the external incision is being made in the cornea, whereby the necessity of introducing a cytotome at a subsequent period in the operation, is entirely done away with. The laceration of the capsule—at the same time that the external incision is being made—is done without any particular difficulty when the pupil is widely dilated by atropine, but it requires a steady hand and some experience to be able to do it successfully when the pupil has been contracted to a

pin's point. When the operation was performed, after previous dilatation of the pupil by atropine, I noticed that there always was a great tendency for the iris to prolapse between the margins of the wound, and that it required to be carefully replaced within, before accurate apposition of the wound could be secured. This difficulty is, however, seldom experienced when eserine is used instead of atropine, for seldom then does a portion of the iris prolapse into the wound, or if it does, it is easily replaced, without the likelihood of its prolapsing again. It is for these reasons that I now prefer to contract the pupil by eserine before operating. I may also add that the formation of a very neat artificial pupil is also rendered easier by this method. Such, at least, has been my experience in the cases that I have operated upon in this manner, and I take the liberty of mentioning these facts, not so much with the idea of advancing a new method, as of inviting the attention of surgeons to give it a trial, and to publish their experience on the subject.

The lens being extracted in the usual manner by means of gentle pressure by a hard, smooth rubber, spoon-curette being made from below upwards over the surface of the cornea. Our next care is to free the pupil of any cortical substance which might have been left behind, as well as to prevent any tag of the capsule or a portion of the iris from prolapsing between the margins of the wound. It is very essential to attend to these points carefully, as neglect of these precautions may lead, not only to the pupil being drawn up to one side, but to the serious danger of repeated attacks of iritis or irido-cyclitis, which may ultimately end in complete loss of vision.

Lastly, the effects of eserine are neutralized by putting into the eye a few drops of the solution of atropine (2 grs. 3i) and a double fold of lint dipped in boric lotion, with a pledget of absorbent cotton soaked in the same, is laid over the eye, which is then bandaged along with the other eye. As a part of after-treatment we are told that a strictly recumbent position should be enjoined for the first two or three days after the operation. No doubt a recumbent position is least likely to disturb the position of the parts within.

I may, however, state that I know of a number of cases where patients in absolute disregard of instructions, have either frequently sat up in bed a few hours after the operation and continued to do so, as often as they liked, or have even insisted upon being walked about in the room, without their eye or the vision being in any way damaged thereby.

A few words about cataract extraction without "iridectomy" will, perhaps, not be considered out of place here. Surgeons have often been known to point out with legitimate pride to the entire circular pupil left by them where no iridectomy has been performed and where the disfigurement or mutilation of the iris (as it is called) is done away with. I have practised this method of operation several times, and have perhaps, like others, been pleased to see a beautiful movable pupil without the gap so frequently noticed in it. I fear, however, that in spite of the pretty appearance of the pupil, this method cannot be recommended for general use, because of the well recognised danger of the prolapse of the iris, which in

spite of a strictly recumbent position has been known to take place even some days after the operation, upon the most trivial exciting cause. The iris thus hanging in the wound, the eye is exposed to the grave risk of "irido-cyclitis," which even follows months after the operation and causes total loss of vision.

The old operation of the "removal of the lens in its capsule," deserves, I think, to be more widely practised than it is at the present day. Iridectomy may perhaps with advantage be omitted in this method, for, when the lens is removed without opening its capsule, there is of course, no possibility of the formation of capsular cataract, or of the soft lenticular matter being left entangled in the iris and setting up violent inflammation in that structure—risks more or less present in the method practised by surgeons at the present day.

—:O:—

IS MAN ADAPTED NATURALLY TO EAT VEGETABLES ALONE?

By P. V. JEHARATNAM PILLAI, C.M.S.

Myore Medical Department.

IN the August number of the *Indian Medical Record* for 1892, the above question is answered by a correspondent in the affirmative, on the sole hypothesis of the "Teeth."

If the structure of the teeth in man be the only criterion wherewith to decide that man is created to be a pure vegetarian, this vexatious question of "What should he eat?" would have ere long been settled and the nature of man would not have rebelled against this provision of Nature of "Vegetable food alone" for him any more than an infant could have an aversion for the mother's milk. For Nature, though a benevolent mother, can never suffer an iota of her laws to be violated, and any disobedience is invariably dealt with due punishment, as there is no forgiveness with her. On the contrary, she rewards obedience with enjoyment and pleasure. It will be seen therefore, that when man violates the natural law, (if there be any), of living upon "Vegetable alone" he would have naturally been punished for his disobedience. But experience has taught us that such is not the case. Hence man's food is not "Vegetable alone."

2. If man is intended by Nature to live upon "Vegetable alone" on the score of his teeth, their structure should be mainly characteristic of the herbivora, having more molars with broad rough surfaces resembling a mill stone, whereas the structure of human teeth is not so. Hence man's food is evidently not "vegetable alone" from a dental point of view.

3. Setting aside then the argument of the teeth which serve in cutting and grinding food, the enquirer should ascertain where the food thus cut and ground goes? As it goes to the intestinal canal, a judicial enquiry regarding the length and capacity of the digestive apparatus should occupy a most important place in the arena of argument; for it is there, in the intestinal canal that the assimilation of food and the nourishment of the animal commences. The carnivora have, obviously a short and simple, and the herbivora, a long and complex intestinal

*Being a reply to an Article which appeared under the same title in the *Indian Medical Record* for August, 1902.

canal. If man had been destined to be purely herbivorous, his mouth would have been provided with four stomachs and a long intestinal canal like most of the herbivorous animals. Again, however, is not the case with man, he is clearly not intended by Nature to live upon "vegetable alone."

4. The theory of a pure vegetable food for man is also impossible of universal application, from the geographical distribution of mankind over the world. Although a Scottish Highlander and a Negro Hottentot are men, yet both live lives as divergent as the North and South poles, just as the fauna and flora of one country differ from those of another.

Man depends for his supply of food on the production of the earth; and to raise which, he has to expend his muscular and nervous energy which also differ according to the demand for food and raiment. In tropical countries, where a high temperature diminishes the quantum of muscular energy, the fertility and productiveness of the soil are increased in like proportion, so that less labor suffices, as the demand for food and raiment is less there. On the other hand, in colder latitudes, where the earth is generally sterile, muscular energy is greatly increased in proportion to the higher demand for food and raiment. Further, the food afforded by the soil in each climate appears to be adapted to the maintenance of the bodily constitution of the people, and to the supply of the muscular energy necessary for the particular wants of the individuals. In the Arctic regions no farinaceous food-grains ripen nor can any vegetable grow owing to the inclemency of the weather. When tourists and navigators to these regions were asked how they, accustomed to the bread and vegetables of a temperate climate, were able to endure the pure animal diet which formed their only support in all their travels, their reasonable answer born of experience, was, "that the effect of extreme dry cold to which they were exposed constantly, was to produce a desire for the most stimulating food they could get; that bread in such a climate was not only not desired but was comparatively unimportant as an article of diet; that pure animal food—the fatter the better—was the only sustenance that maintained the tone of their corporeal system; but that when it was in abundance (the quantity required being much greater than in milder latitudes), a delightful vigour and buoyancy of mind and body were experienced, which rendered life more enjoyable."

In beautiful harmony with these needs of the human frame, these regions abound during summer in countless herds of deer, in rabbits, partridges and also in fish. The flesh of these, dried and stored up, constitutes delicious food in winter when the earth is wrapped in one mantle of snow. Among the Greenlanders and other Esquimaux tribes, nothing is so much relished as the fat of the whale or walrus, while a slice of bread is rejected with strong indications of disgust.

The hot plains of Hindustan are not so favorable for the extensive rearing of sheep, &c., as the cold mountainous regions of Britain, Germany, &c., but produce in prodigious abundance, farinaceous food-grains and vegetables on which thrives with less muscular energy, however, the vegetarian Hindu, to whom the very idea of

eating meat would be repulsive, while to the people of the colder countries of Europe, the diet is and ought to be, animal and farinaceous food, the former predominating; and on such a food accordingly, the European fares best with increased muscular and nervous energy. The inference is, therefore, that man is not naturally constituted to live upon "vegetable alone."

5. If man, on the other hand, is intended by Nature to live upon flesh alone, the formation of his teeth, the structure of his intestinal canal and form of appetite, all would strictly resemble those of the carnivora. As he differs from them more or less in these respects, he is not a purely carnivorous feeder.

6. To the question which would naturally rise out of the above considerations, "What shall be his diet then?" the most cogent answer appears to be that "Man is constituted to live upon a mixed diet," by which is meant a wholesome union of both animal and vegetable food. Man is the most highly organized being in the created world, of which he is the undisputed lord, so that he says with confidence,

"I am the monarch of all I survey,
My right there is none to dispute,
From the centre all round the sea,
I am the Lord of fowl and brute."

God has endowed him with superior sense to adapt himself, as best he can, to the influences of the external world. The three kingdoms of mineral, vegetable and animal over which extends his sway, contribute each their quota to his pleasure and are subservient to his enjoyments. They not only supply him with materials to build a habitation to live in, and manufacture raiment to wear over his hairless soft-skinned body, but also with food to eat.

He has a wide range of choice in the selection of his food, which must come from one or more of these kingdoms. Man uses only salt (sodium chloride) as it is offered to him by Nature, while the other mineral and inorganic matter of which the world is composed are adapted to nourish and support all kinds of vegetables, which supply animals in turn with nourishment; and their flesh again is for the use of others and amongst them, man himself.

7. Man is destined to live upon both animal and vegetable food for the reasons that he has a mixture of teeth, of both herbivorous and carnivorous animals and that his digestive apparatus is less complex than that of the herbivorous and more so than that of the carnivorous. It should also be understood that animal food is more like our flesh and blood than vegetable, and that they are easily digested and assimilated—the like attracts the like.

Animal food is far more preferable to vegetable, inasmuch as the former presents to man nourishment in a concentrated quantity, richer and more sustaining in quality than the latter, from which to derive the like benefits, a very large quantity is required. Is there any nation or sect on the earth, who are purely herbivorous? It has become impracticable even with the Brahmin, the standard specimen of human herbivora, if I am allowed the term, to dispense with milk and butter which, it is needless to say, are animal products, and without which, his food is never prepared and eaten.

* Vide George Combe's "The Constitution of Man," page 45.

8. Before they propose such theories as "pure Vegetable food" for man, its advocates should pause for a while and reflect why man, while it is possible with him to eat and digest *enteria veribus*, any cooked flesh, is unable to treat as, any article belonging to the vegetable world? For, it requires too many poisonous plants to be used with impunity; and these poisonous plants, the animals by reason of their instinct, and men at the cost of their life, therefore, carefully avoid.

9. Whence are these drugs and medicines which appear to be as many poisons to a man in sound health? Do they come mostly from the animal world or from the mineral and vegetable?

What are alcohol and opium—which are dreaded and cursed, by the apostles of temperance as two giant enemies of human happiness, products of—vegetable or animal?

Science and time-honored custom point out plainly then, that man is naturally constituted to live upon a mixed diet, consisting of animal and vegetable food, if the upkeep of his muscular and nervous energy at a normal standard is desirable, although he can sustain life, not of course, in its normal vigour, with a bare vegetable or animal food.

REPORT OF SURGICAL OPERATIONS PERFORMED AND MEDICAL WORK DONE DURING 1894-95 IN THE JUNAGADH STATE HOSPITAL.

By T. M. SHAH, L.M.S.

Chief Medical Officer, Junagadh.

(Continued from page 44, Vol. IX.)

TWENTY-THREE cases of Cancer were admitted:—4 of the breast, 3 of the penis, 2 of the eye, 2 of the lip, 4 of the lower limb, 1 of the tongue, and others affecting different parts of the body.

Of the 4 cancers of the breast, 5 were in females and 1 in a male: 1 female had the tumour removed from the left breast two years before, but it recurred and she was admitted in November 1894. There was no cancerous oedema nor glandular enlargement in the axilla, and no infiltration of the surrounding part, but its recurrence was indicative of malignancy. It was dissected out, the wound healed, and the patient was discharged apparently well.

2. JASAI RAM had a large, deep, foul, ulcerated growth of the right breast. It was removed on the 2nd June 1894, and the patient discharged apparently well on the 18th.

3. PRAKASH had the left breast affected with a large warty, hard growth. It was removed on the 5th December 1894. The wound healed well and the patient was discharged apparently well on the 25th.

4. ANAND CHHEL, aged 67 years, had an ulcerated, hard, scirrhous mass on the left side of the chest with enlargement of the axillary glands; the growth was about the size of a pomegranate. It was removed on the 13th September 1894. Patient discharged apparently well on the 23rd.

These cases of Penile Cancer were treated. First: BHO DEBAR, aged 45, had his whole penis involved in an epithelioma with enlargement of the glands in the groin. On May 1894.—The penis was amputated at its base, the urethra was then separated from the other tissues and left hanging in front of the scrotum. The rest of the stump was skinned over and sutured up. Discharged well on 17th June 1894.

2. KUNDA MATHI, aged 30, had cancer of the anterior part of the penis for 3 months, the glands were not enlarged. 1st March 1894.—Anterior half of the penis amputated. The urethra was then dissected up and left in front of the scrotum, and the penile stump sutured, the patient was discharged well on the 16th March 1894.

3. KALA LIMBA, aged 25, admitted 8th November 1894 with a cancerous growth affecting the root of the penis, glands in the groin enlarged. His penis was amputated a few months before, but the disease had recurred in the stump. The affected portion was excised, then a vertical incision was made in the raphe of the scrotum. The urethra was dissected out, and was sutured to the perineal skin. Patient discharged cured, 10th December.

Cancer affecting other parts.—1. KALA NABSHI, aged 40 had a fungoid mass on the dorsum of right foot on 28th December 1894; it was excised. The patient was discharged from hospital on 25th January 1895.

2. SHAIK MOHAMED, aged 36, had an ulcerated fungoid growth on the left thigh. It was about the size of a coconut, and it was said to have attained this size in 6 weeks; there was no enlargement of glands and no infiltration of the surrounding tissues. On the 25th February 1895, the growth was excised and the patient discharged apparently well on the 1st March 1895.

3. DAYO KANJI, aged 50, had an ulcerated cancerous growth of the size of a lemon on the upper part of the right buttock. On the 30th September 1894 the growth was excised and the patient discharged well.

4. SUNO RUNA, aged 50, had a cancerous growth on the right forearm which was amputated at its upper third on the 17th August 1894. The patient was discharged well on 9th September.

5. ANDEREMAN, male, aged 50, had an ulcerated recurrent growth of the size of a mango on the back. A growth from the same part was removed five months ago. The present growth was excised on the 1st October 1894. An induration is now noticed in the right axilla.

6. L. P., aged 25, suffered from an epitheliomatous ulcer of the upper lip, which was detached over a considerable area and remained hanging in front of the lower lip; the columna and septum of the nose were wanting. Two glands under the lower jaw were wanting. There was no history of syphilis. The ulcer was scorped and an attempt made to replace the lip by union to its original position, but this failed, and the lip had to be subsequently excised.

7. G. R., a female, aged 35, had a nodulated tumour over the hypogastrium, which was removed on the 20th August 1894. She was re-admitted on 1st February 1895 with an ulcerated fungoid growth of the size of a mango, at its former seat. She was anaesthetized and the growth removed again.

8. BODENT ULCER.—GITA PRANOTTAS, aged 45, was admitted on 21st July 1894 with an extensive rodent ulcer situated over the left buttock. The glands in the left groin were enlarged. He was placed under chloroform and the ulcer

several days. He had a sharp attack of dysenteric diarrhoea and made a fairly recovery, and was discharged in October.

He was re-admitted in November with re-appearance of the ulcer of the left buttock, (reaching the verge of the anus); the patient was placed under chloroform, and the tissues affected were thoroughly removed by the knife. Patient was discharged cured on 11th January 1895.

Thirteen cases of *mycetoma* were admitted this year; 8 of them were of the white variety and 5 of the black; 9 of them were in males and 4 in females. In 5 cases legs were amputated, in 2 cases Syme's amputation was performed and in 5 cases excision of the mycetomatous growth was performed; in 12 cases the feet were affected, in 1 the little finger of the right hand as well as of the left hand was affected. She was a female barber by caste. One patient absented.

Naso-Pharyngeal Tumour.—G. B., a child *et.* 10 years, was brought in October 1894 with a large growth in the right nostril which pressed upon the palate and protruded through the posterior nares; the child was placed under chloroform, and the growth removed by an *ectrasour* through the mouth. Its base could not be removed thoroughly owing to its intimate connection with the sphenoid. A large polypus was also got rid of from the anterior nostril.

2. PARBAT, aged 40 years, came in August 1894 with a tumour in the left cavity of the nose. The tumour was hard, the size of a hen's egg. The left nasal cavity entirely filled up the nose and appeared curved to the right. The tumour extended from the root of the nose to the alar margin below, and the malar bone externally.

The patient was placed under chloroform, and a vertical incision was made a little on the left side of the nose, the cartilage cut through, and the tumour gouged out. It arose from the root and anterior wall of the nose and extended nearly to the posterior nares. *Liquor Ferri* was applied to the surface after its removal. The wound was then closed, and healed by first intention.

Injuries.—DAVOOD SALEMAN, aged 36, received multiple injuries by a fall on 10th April 1894. There were three wounds over the scalp, one wound over the cheek, one wound of the shoulder with contusion of the chest and abdomen, and fracture of a rib.

On the 11th urine had to be withdrawn by a catheter. *Emphysema* appeared all over the chest, and the patient died in the evening.

2. JETHO JAGO sustained on the 21st April 1894 a fracture of the left thigh with dislocation of the left knee. The dislocation was reduced, the fracture set, and the limb placed under splints. Discharged well on 24th May 1894.

3. BHANI YASHNAM received on 27th April 1894 multiple injuries by a fall in a stone quarry:—wound on the right temple; second phalanx of the right middle finger dislocated; the lower end of the right ulna was fractured and the right femur was broken at its upper third.

The dislocation was reduced, the fracture set, and splints applied. Wounds were dressed and the patient, who was in a critical state on admission, was discharged well on 24th May.

4. HARSH PARIK, female, was injured by a railway train on 7th May 1894 and sustained a dislocation of the left elbow; fracture of the radius, and a large wound in the left shoulder. The dislocation was reduced and the limb placed in splints. Discharged well on 30th May 1894.

5. BANGORA UMAR, female, aged 35, sustained a compound fracture of the right forearm on 14th June 1894. The wound was dressed and the fracture set. Patient was discharged well on 10th July 1894.

6. RAJO SUBO, aged 35, admitted into hospital on the 18th April 1894 with fracture of the right olecranon. The fracture took place four months ago, and only fibrous union had taken place. A marked depression was found between the olecranon and upper part of the ulna and the forearm was bent. The right forearm could not be extended without the help of the other hand; this forearm fell flat when brought to a right angle, and it could not be extended and brought perpendicularly to the side of the head. The fracture was caused by the blow of a stick.

Operation.—The patient was placed under chloroform, and a vertical incision made over the seat of fracture; holes were drilled above the fragments, which were then united by silver wire. The limb was then placed upon a straight splint, and in the course of a month firm union took place, and the patient gradually regained the power of extension.

7. B. A., female, had an ununited fracture of the right forearm; the limb was swollen and painful, there was no history of an accident. The limb was placed under a plaster of Paris bandage, when the swelling and pain disappeared.

8. MUNA KEMAN received on 5th May 1894 a severe lacerated wound of the right forearm by the bite of a horse. The ulna and radius were dislocated from the right wrist-joint, their ends protruding on the dorsal aspect to the extent of 3 inches; muscles and tendons were torn. The protruding portions of bone were excised and the patient made a slow recovery with a deformed limb.

9. PARSHOTTAM DEVI, aged 10, had a contused and lacerated wound, together with fracture of the right humerus owing to a railway wheel running over it. The parents would not allow any interference with the wound, even when the limb became gangrenous. The child then had tetanus and was removed from the hospital by the parents.

10. **Compound fracture of skull; trephining; recovery.**—On 31st January 1895, P. R., child *et.* 5 years, sustained a fall from a height of 15 feet which caused a wound of the forehead above the right eyebrow. He was conscious. The wound was dressed, but in about half an hour tonic convulsions supervened. The right eye-lid became swollen the muscles of the face twitched and caused distortion of features and foaming at the mouth; the pupils were dilated, breathing became stertorous, and the pulse rapid.

It was evident that there was compression of the brain, most probably due to hemorrhage, as the symptoms of compression supervened some time after the accident.

The child was therefore chloroformed, dressing and sutures were removed, a V-shaped incision made and the skin of the forehead reflected when the skull was found fractured. A small portion of the frontal bone just

where the right splinter was splintered and depressed; another semi-circular line of fracture passed upwards and inwards just outside this line. The pin was fixed and the frontal bone fractured. On the removal of the circular disc of bone, the dura mater was exposed, but no blood clot was found beneath. The dura mater was punctured with the knife, but no extravasation was detected. The depressed splinter of bone was raised and the wound sutured and dressed. Ice bags were applied constantly to the head.

Convulsions ceased after the operation. The highest temperature on the 3rd February 1895 was 100° and pulse 112. They then subsided to normal and the child became conscious. On the third day he took liquid food the bowels were made to act by calomel, and recovery was complete within ten days. Sutures were removed on the 12th February; about $\frac{1}{4}$ a dram of watery, clear liquid ran out of one of the suture openings, but the wound healed by first intention. Discharged well.

One case of *snake-bite* was treated with strychnine injections. Patient was an adult and was bitten during the day time, but the nature of the snake was not ascertained. He was bitten on the leg and a ligature was at once applied above the seat of puncture. When the patient came to the hospital within an hour of the infliction of the bite, he was quite conscious, but a little drowsy with slight thickness of speech. Three injections of strychnine of 15 minims each were given within an hour, after which he began to get twitchings of the muscles; shortly afterwards cold water was repeatedly drenched when the patient evinced rapid convulsions and died.

I am doubtful whether he died purely of snake poison or as the result of the strychnine injections. The value of strychnine as an antidote to snake poison has, however, been exploded by the experiments of Dr. ELLIOT of Madras.

Hydrophobia.—Two cases of this dreadful disease came under observation. One was an elderly man in whom symptoms of rabies manifested themselves on the 30th day after the bite. Emema of milk with lime water was given, also the Bouvason bath, but he died the next day. Another was a child 6 years of age, in whom hydrophobia developed two months after the bite of a puppy. Treatment was of no avail. In both these instances, the dogs were not known to be rabid at the time of inflicting the bite.

Chloroform poisoning; Recovery.—NARAN KALA, aged 3 years, while a vesical calculus was being crushed on the 24th May 1894, became suddenly pale, the respiration ceased, the pulse at the wrist also failed. Artificial respiration and cold douches were continued for 2 minutes but they had no effect in establishing the respiration; electricity was then applied over the cardiac region, while the head was kept hanging over the edge of the table, and artificial respiration resumed. In about another minute, a gasp was observed, a few seconds after another gasp took place, and gradually, regular respiration was established and the color of the face began to appear, but on relinquishing the electric treatment again to fail. Efforts were therefore made to induce vomiting, the boy was brought back from the very jaws of death.

He then vomited copiously, and a gasp was observed, and stating that the ball had come off the head of the boy. The child was then given a mixture of chloroform and ether and the operation was quickly completed by lithotomy.

2. K. R. was nearly dying of chloroform poisoning during a stone operation on 29th August 1894. Respiration ceased on replenishing the chloroform inhaler. Artificial respiration, electricity, and the cold douch were persistently applied for five minutes and succeeded in establishing the respiration.

Aneurism.—A. N. was admitted with a large tumour about the size of a cocoanut in the upper part of the right side of the chest and neck. On October 3rd 1894 the clavicle was "buried" in it. It was pulsating and evidently aneurismal. It was daily increasing in size. Extending down the chest and towards the axilla it measured 28 inches in circumference. Iodide of potassium was given internally, as operative interference was out of question owing to its situation. Pressure could not check its growth, and it was painful. Patient could not sleep. Twenty minims of liquor ferri perchloride were injected into the sac, whereupon the patient immediately dropped dead.

On *post mortem* examination a coagulum was found in the left ventricle and the aneurism arose from between the right carotid and innominate arteries.

Rhinoplastic operations were performed on 32 patients, 4 among them being males and 28 females. In one of them (male) rhinoplasty had been performed at another hospital, as a result of which the nose was deformed and the nostrils closed; in the present operation the nostrils were re-opened.

In the three other cases reparation was made by cheek flap, while in all the 28 female cases the forehead flap was utilized for repair.

In 27 cases the nose was cut off by knife or razor, in 2 by nut crackers, in 2 it was bitten off, and in 1 it was cut off by a sword.

Cheiloplasty, or reparation of the lip, was made in 4 cases. In two cases the lip was repaired by dissecting up a flap from the cheek, and in the other 2 the everted upper lip was brought down by incising the cleatrix and grafting in skin in the gaping wound.

A MIRROR OF PRACTICE

A CASE OF TETANY (?)

By JOE P. BARDOZA, M.B., D.M. (Edin.)

Medical Officer, North Mysore Planters' Association.

THE following case showing very marked and curious nervous symptoms, came under my observation. I do not presume to a definite diagnosis, but content myself to describe the signs and symptoms, with the progress and termination of the disease.

My patient was a thin sparely built girl of a nervous type, nine years of age, and with no previous history of serious illness. There was no family history of any nervous disease—Alcoholism, tabercle or syphilis. No signs of ear disease or rickets could be detected, and there was no suspicion of intoxication by arsenic or strychnine. The child was pale, thin, and nervous.

On the 10th of January, she had an attack of illness lasting five or six days, when giddiness, vomiting, hunger, and fever of a low type were the chief symptoms. She had two more such attacks in February and March, with some pain and swelling in the gums and tonsils and glands of the neck, superadded to the other symptoms. There was also some unsteadiness of gait, she was apt to stumble on rising or walking. These attacks also lasted about a week. She was well in the intervals.

History of present attack.—On the 16th of April, in the afternoon, the child grew languid and drowsy, complained of muscular pains, later on she felt giddy, vomited and had some diarrhoea. She was weak and kept to her room. The next day she entered on a new phase of her illness. She had what is described by her friends as momentary fits of unconsciousness, which I depict elsewhere as the "petit mal". On the third day of her illness, in the afternoon she said, "she felt cold." A minute after she fell back into a convulsive seizure which I shall call for convenience sake, the "grande seizure". The fit lasted half an hour. She woke quite well and cheerful, and on being questioned denied any knowledge of what had happened. The fit was repeated in the afternoons of the next two days. For three days afterwards she had no fit, but complained of her old symptoms. For the next five days she had a fit every day and complained of some pain in the spine in the cervico-dorsal and upper dorsal regions. Twice at the closure of the seizure she woke up laughing and suffered from hallucinations, calling on imaginary babies to play with her. She had no seizures for the next four days, but still remained unsatisfactory otherwise. She could not be trusted alone for fear of stumbling and falling. She seldom walked, as she was very unsteady. On the 30th of April she took fright at a barking dog and the next day she once more had a fit. She was then placed under my care.

Examination.—The child seemed very ill with a shrunken face, puffy lids and dark rings round her eyes. She was anæmic. Her conjunctivæ were slightly yellow. She was timid and irritable, could be induced with great difficulty to walk, and then she stumbled from weakness and giddiness. There was no inco-ordination of muscles, which were tested. The tongue was furred, yellow and slimy. The bowels loose and variable in color and appearance, and very offensive in smell. There was some pain round the navel on pressure, and vomiting was present after food. The vomiting was effortless and spontaneous, only a small and evidently the last portion of each meal being ejected. She complained of languor and weakness, headache and a feeling of tingling and numbness in her legs. Her sleep was good. She was never disturbed by a fit at night.

On physical examination.—Nothing special could be detected, the pupils were normal and acted well. The reflexes were not altered. The heart was weak in action. The pulse was small and soft. The skin was dry, rough and sticky to touch (as on the legs and arms). The urine contained some albumen. The condition of the thyroid was not altered.

Special notes representative of studying the case, and I shall describe the treatment and its results. During the

course of the day the child, who appeared frightened and fagged, would, while talking, or playing, fall back with eyelids tightly closed, a collection of frothy saliva would gather round the mouth which would flow away. To the casual observer she seemed perfectly unconscious and rigid. She could however be roused and resisted angrily any attempts to awake her or to open her eyes, and if it was persisted in, she would moan and cry in a half-conscious manner. The face was calm and placid if undisturbed, and of ordinary colour. The legs were often extended rigidly and the toes pointed; but no clonic spasms ever occurred. In 2 or 3 minutes she awoke, often with an angry exclamation at her helplessly condition, and would accuse somebody of throwing water on her. She generally had two or three such attacks a day. This fit I call the *petite mal* in contradistinction to the grand seizure I am about to describe.

The *grande* was always ushered in with a feeling of chill, persistent yawning or hiccups. She then passed through the *petite* stage to one of convulsive spasm. The muscles of her face twitched occasionally and her arms were slightly adducted to the sides of her body or crossed over her abdomen, the wrists flexed and her hands clenched with the thumbs turned in, while the muscles of the arm were thrown into fine rhythmic contractions. The legs were held rigid, the ankles extended, and the toes flexed into the soles of her feet. No clonic contractions occurred here. The pupils were normal and her pulse unaffected. The respiration was unaffected except when harassed by the hiccups. There was in addition the frothy saliva of the *petite* stage. The seizure lasted 20 or 30 minutes, hiccups or yawning terminated the fit, and she woke up in a half-dazed manner.

Very often violent and convulsive hiccups complicated the seizure throughout; or took its place. On one occasion this became so frequent, noisy and crowing that it became alarming. It lasted over a very distressful hour and was not controlled by chloral, bromides, musk or large doses of ergot. I chloroformed her and was then successful, only when I proceeded to deeply narcotise her. I feared a fatal ending from prolonged spasm of the diaphragm and failure of respiration. She had to be kept deeply narcotised for 15 minutes and then allowed to sleep it off.

These fits occurred in the afternoons, and she was the better after them, being less drowsy and more cheerful. These different phenomena could be averted if her attention was sufficiently diverted, and on one occasion I stopped a "grand" seizure by vigorous dashing of cold water and the moral control of her father.

During the course of my observation, her unsteadiness of gait terminated in utter inability to walk, and she could not be persuaded even to stand on her feet. She said her feet tingled, and if forced to put them to the ground, they developed a hysterical variety of talipes varus.

Progress of the case and treatment.—Careful treatment by purgatives, dieting and vermifuges disclosed no worms. Bromides in large doses had no effect. Chloral, musk and other sedatives also failed. I was then led to try, as far as it was possible in a sympathetic household, the force

of mental treatment, cheerful companionship and the instilling of self-confidence. Frequent doses of castor oil cured the gastric irritation. I then put her on Parriah's food and large doses of Fowler's solution, 5 to 10 minims twice daily. The "grande" seizures stopped. She gained confidence in standing and walking. Her tongue cleared and she began to look more like herself. The hiccups in a modified degree persisted and the saliva collected frothily during sleep. Her temper was still irritable. The characteristic vomiting was seen occasionally. On the 15th May she was up and playing but was subject to hiccups and other minor evils. I have since heard that she had one seizure very slightly but is otherwise well now, but parent is fearful of recurrence.

Observations on the case—Such varied symptoms are usually ascribed to worms, and in such cases of children in India one first explores that hypothesis. Your readers will observe points in the history and description as given by the relatives, which would suggest "Epilepsy." This disease often makes its first appearance in childhood. The unconsciousness was however, not perfect, and the foaming but an excessive salivation from some reflex cause, the saliva being half consciously churned up into froth. The fits and the expression of the face were unlike those of epilepsy. The clonic spasms were bilateral, peculiar, and confined to the upper extremities, while the lower showed rigidity. There was no biting of the tongue or any other injury sustained. There are other points in the history, &c. I need not dwell on. Tetany, I presume is a rare disease in India. Certain points in my case point strongly to it. The "grande" seizure is characteristic of the spasms of tetany. The feeling of tingling and numbness in the legs, the inability to walk, the gastro-intestinal irritation, &c.

The subject was such as is prone to tetany, viz., "anaemic, nervous, and excitable." The spasms were not controlled by hot baths, bromides or other sedatives, nor by chloroform (unless pushed dangerously) but were amenable to cold douching. There were however, no signs of rickets nor did I elicit the signs given by TROUSNEAU and ARERCHOMIE. The thyroid was unfortunately not examined. The other symptoms as "hiccups, giddiness, salivation, dryness of skin and scaling, puffiness of lids, &c." may be explained by the theory of implication of the thyroid, derangement of whose function sets up the disease. DR. BYRON BRANWELL of Edinburgh and GOLSTEIN of Leipzig aver- atrophy of the thyroid and the suspension of its functions, with perhaps a circulation of a mucin-like substance as a cause of tetany. There is very little doubt that the Thyroid has important functions as a burnisher of the nervous mechanism. They advocate a thyroid extract treatment.

Lastly, there is a disease erroneously confounded with malingering and the "dernier resort" of the puzzled and baffled physician. Hysteria, a disease unfortunately becoming very common in these go-a-head days. There is much in the varied and varying symptoms and in the moral treatment of the case that is highly suggestive. Objections in respect of age are not unanswerable. Neither age nor sex is a barrier. It attacks the growing girl and the maiden boy; the sentimental maid and the impressionable youth; while the faded matron and the graven crone are not exempt.

HEPATIC ABSCESS: INCISION: RECOVERY.

By ASSISTANT-SURGEON H. M. PANDORI, A.M.S.

Gondar.

PANDORI, H. M. *et.* 30 years, suffered from malarial fever off and on for two years. Notwithstanding this he enjoyed fair health till about a month before his admission into the hospital, when he got an attack of bloody dysentery, which lasted for ten days, towards the close of which the patient felt some vague sensations of pain in the hepatic region, and occasional shivering fever. He was brought to the hospital on 10th June 1895. He was pale and considerably emaciated, but did not seem to attach much importance to his hepatic trouble. He had come to be treated for general weakness, as the result of long-continued malarial fever. His sclerotics were slightly jaundiced and his pulse febrile. The patient complained of slight cough and pain on the right side of the chest on coughing. Superficial examination revealed some fulness over the hepatic region, and on examining more closely, the liver and the spleen were found to be enlarged. Some deep fluctuation was also detected over the liver.

Taking the previous history and the present condition of the patient into consideration, it was not difficult to form an opinion about the nature of the case, and the exploring needle soon settled the matter definitely. The patient was at once put under chloroform and a free incision made in the interspace between the 9th and the 10th ribs on the right side. About four pints of thick pus was removed. The abscess occupied the right lobe of the liver, and on introducing the finger the walls of the abscess-cavity could not be reached in any direction. The cavity was thoroughly washed out with carbolic lotion and a large drainage tube inserted. Improvement set in rapidly from the time of the operation. The temperature remained normal till the 24th, when it went up suddenly to 104°, going down to normal again next morning.

The abscess-cavity was daily irrigated with iodine lotion—which I find in my practice the best and the most efficient antiseptic lotion for checking discharges. The cavity went on healing without any interruption, and the patient was discharged cured, on the 6th July. He had improved wonderfully, and the spleen had also gone down in size.

—:—

TWO CASES OF CASTOR-OIL POISONING.

By BANKIM BEHARI CHATTERJEE, L.M.S.

Bali.

For the benefit of other practitioners, I give the following two cases of castor-oil poisoning which came under my treatment:—

The seeds of *ricinus communis* contain an active principle called *ricin*, which if not extracted from the oil and used pure, produces severe gastro-enteric disturbances, viz., vomiting, purging, collapse and even death. The ordinary benzoin oil contains the same irritating substance, and on an account should it be given internally.

The drug vendors now-a-days, without looking to the safety of the patients, sell the ordinary oil, at a cheap rate. The oil is simply filtered through blotting paper.

The ignorant people buy it for its cheapness and suffer in consequence.

Two cases are cited in illustration.

Case No. 1.—On the night of the 14th October 1894 I was called to see a Hindu boy, aged about 2 years. The father stated that a dose of ordinary bazaar oil had been given to move the bowels.

I observed the following symptoms :—

Patient discharging bloody stools with great pain. Pulse quiet and compressible, voice inaudible, intense thirst, and restlessness. The extremities were cold but the temperature in the axilla was normal.

Treatment.—Ice to suck ; perfect rest. A mixture containing bismuth and hazeline was given within half-an-hour ; the boy voided 4 more bloody stools and collapsed with a cold and clammy perspiration all over the body ; pulse nil at the wrist. Temperature 95° F. in the axilla.

Friction with fingers all over the body and other measures to generate heat were adopted.

Pulse and temperature gradually came round to their normal standard.

The boy after all made a recovery.

Case No. 2.—A Hindu boy, aged about 6 years, was suffering from an attack of acute dysentery. To clear the offending materials from the intestine, a dose of castor-oil was given with the result that violent gastro-enteric disturbance at once ensued.

The bloody stools and vomiting increased in number and frequency. In spite of very energetic treatment adopted the child died of exhaustion and gangrene of the bowels.

Remarks.—My object of bringing these two cases before the profession is with a view to the sale of impure and adulterated drugs being checked by law owing to the troubles they bring upon both the patient and physician.

AN INTERESTING CASE OF SUDDEN AND FATAL DIABETES.

By JAMES HARRIS, L.M.S.

Madras.

A STRONG powerful man of forty was seen walking about the street, to all appearance in perfect health, only five days before he sought medical aid. When he saw me, he complained of extreme weakness brought on, as he thought, by frequently micturating the previous night. He suspected, he said, sugar in the urine some days ago as the ants were attracted by it. His expression was troubled and indicated great anxiety. The heart was weak and excited. The full expansion of the lungs wanting, the respiration was shallow. The muscles once hard and defined were soft and shapeless. The urine was light with a specific gravity of 1030. Contained sugar—about 12 grains to an ounce. *There was no acetone.* I put him at once on codsea combined with sulphate of zinc, arseniate of quinine and nux vomica, which I have found to be of invaluable use in almost all similar cases. The next morning the patient, being unable to see me in my rooms, sent for me. I was surprised to see him so reduced in 24 hours. He said he passed urine in large quantities almost every 10 minutes. His thirst was painfully unbearable. The occasional sipping of a little glycerine allayed it a little. Small quantities of broth with a teaspoonful of brandy were ordered every hour.

In the evening the patient was lying thoroughly helpless. *Pulse* weak and small. *Respiration* shallow and hurried.

The third morning the specific gravity of the urine was 1025. The patient became unrecognisably thin. His speech was a whisper. He recognised friends by signs. A stimulant mixture revived him a little. I visited him at 11 A.M. to see him dying. He was conscious until the last moment. There were no symptoms of the usual coma in diabetes. The rapid loss of the functions of the vital organs brought on by the incessant uncontrollable drain on the system so unexpectedly closed the scene.

The following can be surmised as the cause of this painful end :—

(1). He was for some time in great mental anxiety occasioned by the loss of some jewels, his sole treasure on earth.

(2). He was already diabetic, though in a mild form.

(3). As the exciting cause of this uncontrollable discharge of the urine can be mentioned the sudden change of the weather from extreme heat to cold by an unexpected shower. Many complained of the effect it had on their kidneys, but while in them it was only a physiological phenomenon, proved disastrous in the case of this unfortunate patient.

A CASE OF YELLOW OLEANDER POISONING : RECOVERY.

By ASST.-SURGEON ROMANATH DEY, M.B.

Madaripur.

M. A., Hindu female, aged about 25 years, was brought into hospital by her husband on the 4th July 1895 at 10 A.M. in a state of collapse, suffering from the symptoms of acute yellow oleander (*Thevetia Nerifolia*) poisoning.

The patient on admission stated that as she was suffering from flatulency and constipation for a couple of days previously, she had taken that morning a bit of the seed of the fruit of yellow oleander with a belief that this would move her bowels and relieve flatulency. About half an hour after she had taken the seed, she began to purge and vomit, and in a short time became thoroughly prostrated. Her husband then had her removed to the hospital.

Condition on admission.—Body covered with cold and clammy perspiration. No pulse at the wrist. Pupils dilated. Voice very feeble. Frequent nausea and vomiting with severe pain in the stomach, was rather drowsy.

Treatment.—The stomach was thoroughly washed with stomach pump and hot bottles were applied to the extremities. Stimulant mixture was given every hour, but this could not be retained for the first two or three doses. Spitz's half a drachm was injected hypodermically once at 11 A.M. and again at 12 noon. At 1 P.M. the pulse was faintly perceptible and the body became gradually warm, but the vomiting with pain in the stomach continued still, as no eggs were available at the time, milk thickened with barley was given at short intervals, which to a great extent relieved nausea and vomiting. At 2 P.M. pulse became distinctively perceptible and vomiting was less than before ; 4 P.M. the same ; 6 P.M. pulse good and regular, vomiting and pain in the stomach less ; 9 P.M. vomited once. During the rest of the night vomited twice, and was rather restless.

5th July.—Had one soft feculent stool at 6 A.M. No vomiting. Pupils dilated still. Since then she made an uninterrupted recovery and was discharged cured on the 8th July.

Remarks.—Poisoning by *Nerium Thevetia* is very rare. I have seen only one other case, about 12 or 13 years ago, in a lad who died from its effects, and on whose body a post-mortem examination was held by my revered uncle Rai Kanny Lal Dey Bahadur, C.I.E., when he was Teacher of Medical Jurisprudence in the Campbell Medical School at Calcutta.

The poisonous nature of the drug was up to this time quite unknown to the people of this part of the country.

THE Indian Medical Record.

16th August, 1888.

SIR WILLIAM ROBERTS, M.D., F. R. S., ON THE
GENERAL FEATURES AND THE MEDICAL
ASPECTS OF THE OPIUM HABIT IN INDIA,
AND THE RECKLESSNESS OF THE
EVIDENCE ON WHICH HIS CON-
CLUSIONS ARE BASED.

III.

The opium habit and food.—That any beneficial relationship, apart from medicinal uses, should be traced between opium, a narcotic poison and food, was left for the Royal Commission on opium to discover. It will amuse the readers of this journal if it does not interest them, to follow the medical expert in his endeavours to explain and defend the beneficial effects, which he maintains, the starving ryots of Orissa and Assam derive from the use of "opium as an economiser of food." We omit the Bengal ryot proper advisedly, for he has not yet learned to avail himself of this drug as a food accessory, to ameliorate his hard lot. This subject is referred to as follows in the medical memorandum. "The Commission were frequently told that people who were well off and had plenty of good food tolerated the opium habit with impunity, whereas the poor with an insufficient supply of food suffered from it. On the other hand, we were often told that opium ameliorated the lot of the underfed man and enabled him to live longer and better with a scanty diet." Or that the half-starved ryot—able in times of scarcity to obtain only one meal a day—is not only benefited by eating opium, but that the opium habit "ameliorates his lot" and enables him to live longer and better with a scanty diet! It will help us to appreciate the worthlessness of this statement and enable us to estimate it at its true value, if we trace it to its original source. The earliest medical reference to opium in relation to food in India, is found in a paper written by Dr. VINCENT RICHARDS, who was Civil Surgeon of Balasore in Orissa. He found the opium habit very prevalent in Balasore, and inferred that the people had acquired the habit during the terrible famine of 1866. Apparently, he was not aware that the habit of opium-eating in that district dated back to the time of the East India Company, when opium was cultivated in Orissa. It was in 1778 "that WARREN HASTINGS, Governor of Bengal, assumed on behalf of the East India Company a monopoly of all the opium produced in Bengal, Behar and Orissa." (East India Opium, page 22). The habit had existed and was widespread in Balasore, as it is at the present day, long before the famine of 1866: but Dr. RICHARDS finding the ryots addicted to the use of the drug, could only account for it by supposing that the hungry ryot began it to allay the pangs of hunger. No doubt he found some who had little means wherewith to buy food, spent part of that little on opium—for next to the cravings of hunger itself must be placed the unnatural cravings of the opium habit—but to suppose that the starving ryot, unable to buy food for himself and his family,—and who had never before used opium—

should begin the habit with his last few rupees, is not only highly improbable, but manifestly impossible. The starving ryots had neither money nor food during the famine; (opium is dear in that province) and we are not aware that the British Government ever ordered the free distribution of opium during that or any subsequent famine, to alleviate the miseries of the starving ryots. The absurd theory of opium as an "economiser of food" was thus generated in error, fostered by official interest, and is sought to be made acceptable to the public by SIR WILLIAM ROBERTS in this Medical Memorandum. This newly discovered and unlooked-for beneficial property of opium was at once eagerly seized upon as a plea for justifying the existence and furthering the extension of the traffic in the drug. Its virtues as a dietetic, its potency and staying powers were voiced loudly by medical officials in the press at home and in India, culminating in the astounding verdict of the memoirs before us—a monument alike of misguided talent and biased judgement—"that opium ameliorated the lot of the underfed man and enabled him to live longer and better with a scanty diet."

The evidence taken from the lips of a retired Deputy Collector, himself a native of Orissa, who was on relief duty during the famine of 1866 is conclusive on this point. Question: "Did you ever hear the starving people ask for opium to allay the pangs of hunger?" Answer: *No, I never heard of that, their one cry was "rice! rice!" &c.* The theory of opium as an economiser of food is clearly traceable to one of those careless, thoughtless, absurd statements frequently found current among irresponsible and superficial observers; but which should never find a place in the pages of the Report of a Royal Commission. To compare opium with alcoholic beverages and tea and coffee will not bear examination. The fluid and bulky form and the nutritious and stimulating properties of these food accessories as used in Europe, render comparison with the nervous narcotic—the bulk of which is only a few grains—inadmissible. The effects of opium are purely nervous, that of tea, coffee cocoa and alcoholic beverages, as used with food, stimulating, and satisfying because of their bulky form occupying a large part of the space allotted to food in the stomach. Opium, on the other hand, by its inhibitory action on the secretions of the stomach, and its paralyzing influence on the peristaltic movements of that viscus, hinders its due performance of the digestive function. Dr. BURNEY YEO notices this action of opium as a possible cause of gastritis. He says: "The continued use of narcotics, such as opium, by diminishing both the secreting and propelling forces of the stomach may lead to retention and abnormal decomposition of ingesta and so excite gastritis" (Manual of Medical Treatment, page 46). We have frequently conversed with opium eaters, but we never found any one of them even hint that opium economised his food, except in the way of diminishing his scant income and thus leaving him less for food for himself and his family. Any encroachment on his food-supply speedily tells on his own constitution and that of his starving family. The chronic constipation and emaciation which accompany the opium habit are doubtless in some degree

equated by the kind of food stuffs which the well-to-do opium-eater can afford to procure, viz.—milk, ghee and *subulmanis*. It is not, however, altogether on that account that milk is selected as a necessary article of diet, without which the opium-eater soon shrivels up; it is rather on account of the inability of the stomach to deal with large quantities of rice and vegetables, which constitute his daily food. We cannot do better than quote Sir WILLIAM ROBERT'S own lectures on dietetics to explain the reason why milk is selected by the opium-eater as a necessary and almost exclusive form of diet. Writing of gastric and intestinal digestion he says: "*In the seriously sick (and opium-eaters) with an almost paralysed stomach milk is not meddled with in that vianus. There is neither pepsin nor acid to curdle it, and it passes as a flowing liquid into the duodenum. Arrived there it encounters the secretions of the still active pancreas, and as I have before remarked, milk is especially amenable to the action of the pancreatic juice.*" This seems to be the true explanation of the opium-eater's preference for milk as an article of diet when he can get it.

Another theory—a favorite one with the writer of this memorandum—is that opium is resorted to by the ryots of Bengal on account of its retarding action on the contents of the stomach.

Dr. COBB, who succeeded Dr. CROMBIE as Civil Surgeon of Dacca, has the unique distinction of making this original observation on the poor ryots of Eastern Bengal—the very districts where the malarial intensity, according to Dr. CROMBIE, necessitated the ryots to possess opium as a household remedy. The observations of Dr. COBB are so fully in accord with Sir WILLIAM ROBERT'S views that we place them side by side, so that the reader may duly appreciate the similarity which is striking and suggestive:—

Sir William Roberts: "For to express the problem in another way it may be said that we render the food by preparation as capable as possible of being completely exhausted of its nutrient properties, and on the other to prevent this nutrient matter from being wastefully hurried through the body we make use of agents (tea, opium, cocaine, alcoholic beverages) which retard the speed of digestion." (Lectures page 65).

Dr. Cobb: "In the damp climate of Eastern Bengal the poor Natives are in the habit of eating largely of rice and a peculiar sensitiveness of the bowels seems to exist in those damp climates. As a man advances in age digestion falls to some extent, and the food is hurried through the intestines. . . . The effect of hurrying food through the intestines is to cause diarrhoea, dysentery and other allied affections. Opium, in small doses prevents this, and it is largely used by the poor in Eastern Bengal."

In dealing with Dr. CROMBIE'S theory of opium as a household remedy we shewed that 1,106 well-to-do opium-eaters, scattered among the six large towns with an aggregate population of 110,000, would account for all the opium consumed in the district of Dacca. The same applies to Dr. COBB'S theory of opium as a retarder of digestion. The ryots do not use opium for any such purpose, for the simple reason that they are not and never were opium-eaters. It is difficult to account for such evidence being seriously placed before the Royal Commission on opium; and equally unaccountable why Sir WILLIAM ROBERTS did not perceive that the evidence tendered by Drs. CROMBIE and COBB was contradictory and mutually destructive. Both witnesses put forward different theories to account for the same habit among the same people and in the same district. The former ascribed the use of opium as a prophylactic to the intensely malarious environment; the latter, only to aid

the failing digestion of advancing years, and both endeavour to account for a habit which does not exist among the ryots in that district outside the city of Dacca itself and the five larger towns scattered over the district.

Still further to strengthen his diastolic theory, He quotes Dr. ELIZABETH BRILLY as stating that "it was a general practice in the Punjab for women to take a small dose of opium (about one grain) just before or with their midday and evening meals as a digestive." But the medical expert might have gone further and asserted that no opium-eater or smoker could take food without first satisfying the opium craving—it is invariably taken before food, but not as "a digestive." The opium constitution generated in the opium-eater is the most imperative and commanding appetite known. As soon as the hour of indulgence comes round, unless the drug is obtained, the opium-eater or smoker is unable to put forth the slightest mental or physical effort. A witness in the witness box, in the midst of his examination, breaks down without it. A whole ship's crew of opium-smoking Chinamen have been known to endanger the safety of the ship and all hands strike through sheer inability to work after their stock of opium had run down; and in such circumstances the medical stock of opium in the medicine chest had to be divided among them to enable them to work the ship into harbour. That is the only relation which opium bears to food and to work. It is neither a "digestive" nor a stimulant to those who have not formed the habit, but keeps the opium slave from sinking down into utter physical and mental helplessness, and drags him up to the low level of his feeble and enervated existence.

Relation of the opium habit to the generative function.—

Rightly or wrongly, the people of India have implicit faith in opium as an aphrodisiac. As such this drug is resorted to when the sexual energy begins to wane, about the age of 45 or 50. It will be found that the habit of eating opium is usually begun about middle life, but smoking opium seems in India to be a habit that is begun at a much earlier age. Sir WILLIAM ROBERTS admits that it is largely a habit of middle age. He says: "It must be remembered that the opium habit is in the main a habit of middle life and advancing years, and is not often practiced in youth and early manhood." Thus shewing clearly that the habit bears no direct relation either to malarial or damp climates on the one hand, or to dry and salubrious climates on the other. It may therefore be accepted that those who have not begun the habit for the alleviation of some painful disorder, such as rheumatism, syphilitic or non-specific, have taken to the habit under the belief that the sexual function would thereby be invigorated and the impotence of advancing age warded off for a time. How far their expectations have been realised by actual experience is a question into the merits of which we do not enter here. Suffice it to say that whether it is that the opium habit leads to sexual indulgence, or that sexual indulgence incites to begin the opium habit, the fact remains indisputable, that the habit is usually associated with the gratification of the lower animal passions. Comparing the diminished fecundity—1½ child for each person—among opium-eaters with the very high birth-rate of 42 per 1,000 in India, the WILLIAM ROBERTS is at a loss to reconcile the seeming anomaly of

these figures. He offers as an explanation that "the congress of the sexes takes place very early in India, and chiefly before the opium-habit has attained much development." This is not the true explanation. If the opium habit were general and widespread among the teeming millions of India, the diminished fecundity of opium-eaters would doubtless affect the national fecundity by lowering the general birth-rate; but the habit is far from general outside the present and past opium-growing regions, and may be said to be limited to a few well-to-do middle aged debauchees, leaving the great mass of the agricultural population as yet untainted with the vice. The policy of the Government by placing licensed shops within the reach of every village, extolling the virtues of the drug as a panacea in every conceivable ailment to which flesh is heir to, is speedily changing the whole aspect of rural India, which must soon imitate the vices and depravity of the cities by indulging in a costly vice that saps individual and national character, degrading and impoverishing its victims as no other vice does.

—:o:—

THE PHYSICIAN AND THE PRIEST.

CLOSELY allied to the consideration of the physician as a moralist is the question of the relationship that should exist between physicians and ministers of the gospel. Just as the moral good is linked with the spiritual welfare of communities, so do physician and priest stand, as it were, on common ground, having in many respects much the same objects. And as morals are to a greater or less extent, affected and influenced by mental and physical weaknesses with which it is the duty of the physician to deal, it is meet and proper that there should always be attempted a cultivation of the best of relationships between medicine and the church. It is very much to be regretted, however, that this desirable relationship between the members of one and of the other does not exist to the extent that may rightly be expected. In fact, discourtesies are not infrequent: and only too often a very strained and formal appearance of mutual good feeling is maintained. We must admit that the church is invariably well disposed to our profession; and if the profession is not always discourteous to the gown, it unfortunately very often betrays a touchiness, and is very prone to regard as unwarrantable, intrusions on its province, or as personal insults, many acts and attentions which ministers know it to be their bounden duty to perform towards the sick and suffering of their faith.

The mutual relationship between the two professions is at a fairly amicable standard ordinarily; and even in sick chambers of private homes, any demonstration of offence on the part of one or of the other, is controlled out of deference to the wishes of relatives and friends of the patient; but it is in some public institutions—scenes to which the voice of duty summons members of the two callings in equally strong terms—that offence is generally taken, and leads to the discussion of rights and privileges, and of wrongs, supererogations, and intentions that may, by proper reflection and consideration, be avoided. The uncertainty of life and the necessity for being ever ready to meet the "Master's call" are conceded to be

unquestionable: yet when our fellow beings are in the grasp of serious and dangerous illness, and their lives appear to be in the balance, and when in consequence, the spiritual preparedness is all the more desirable, the physician in his zeal and ardour for the restoration of the physical powers of his charges is prone to repress, to some extent at least, those all-important spiritual ministrations of churchmen. Such repression on the part of the medical profession arises almost invariably from the idea that the visit of a minister will be disturbing to the patient, or be suggestive of his case being hopelessly bad, and hence alarming. We do not mean to affirm that it is the universal rule with physicians to endeavour to restrict the visits of ministers to the bed of sickness; nor do we mean even to hint for a moment that physicians, as a rule, have little regard for the spiritual needs of their charges. What we say is that, in many instances, a physician's solicitude for the physical well-being of his patient, and perhaps for his own professional reputation, makes him assume the role of regulator of the actions and duties of ministers. With regard to the minister's visits being disturbing to a patient, we may say that, even if they were disturbing, such disturbance is a necessary evil. Surely ministers are not unreasonable beings. They have a Christian solicitude for the recovery of the sufferer, and will be careful not to worry him more than duty demands. That it is likely there will be found a priest or minister whose zeal may lead him into more than necessary interference with, or disturbance of, a patient is no more justification for the rule that a physician should control the actions and visits of pastors to the sick bed than that physicians should be stigmatized as actually ignoring the spiritual needs of patients, because a few physicians may be found blind and deaf to Christian doctrines. As to the pastor's visit occasioning alarm to a patient as suggestive of his approaching end, we think that this is a mere fancy. Except some painful affection is terminating existence, there appears to be no pain in dying. Most or all of those who have risen from beds of serious illness, in which the end seemed imminent, will almost invariably assert that they experienced no dread of death; and that even with the knowledge that they were in a critical condition, they felt none of those dreads and alarms usually thought to beset the dying. In fact a physician has lately given it as his experience that in the last stages of existence in fatal illness there is experienced a calm composure, and a pleasantness, to feel which, it is worth one's while to go through a bed of serious and painless illness. We do not, however, advise the experiment, nor do we attempt to argue the exactness of the sensations attending those prostrated by sickness, but conventional ideas as to the dire thoughts and painful anxieties afflicting the patient who suspects that his present sickness will be his last, are far from being correct. The dying Christian, then, who has been in communion with his church, always welcomes, even more than he did in health, the visits of his pastor; while to the less godly ones, those visits are received with undisturbed indifference, or bear fruits of self-reproach for the past and amendment for the future. All this may read like a homily, but it is relevant so and closely connected with the consideration of the subject.

in hand, viz. the relationship that ought to exist between physicians and spiritual pastors. As we said before, it is in public institutions under the control of medical men that one is most likely to witness little brushes and frictions between members of the two professions under notice; and we can cite a few instances in which physicians have behaved with downright discourtesy in the wards of our hospitals to priests and parsons. Some physicians of our hospitals assume too much of the rôle of lords and masters of these institutions. They appear to lose sight of the fact that these are public places, to which a public duty calls them and ministers alike—institutions which Christian charity has called into existence, and in which the presence of physician and priest is equally imperative and essential. In fact much of the dread that a patient often evinces to seek admission into a hospital when he is seriously indisposed, is due to the idea that he is likely to be allowed to die there spiritually neglected; and the slightest friction between physician and minister in hospitals is likely to foster that idea in the public mind. Far be it from us to impute boorishness to our hospital staffs, or to impeach the general kindness and courtesy of our profession; but in a few instances in civil and military hospitals, when the province of the physician was supposed to have been intruded upon, or when occasion for offence (if offence it can be called at all), was most unintentionally given by visiting ministers, we have known medical officers to express their displeasure in very hurtful and objectionable ways, instead of talking the matter over in a friendly spirit. It is certainly a great satisfaction to know that these cases are exceptions to the rule; but these exceptions have been rather too frequent to be allowed to pass unnoticed, and must be harmful to the credit of our charitable institutions for medical relief as well as to the profession at large. Cases of this sort should scarcely ever occur; and they certainly will be very few and far between indeed, if physician and priest and minister always kept before them the fact, that the interests of their callings lie more or less in the same directions, and that Christianity demands that they should help each other in their ministrations.

SOME THOUGHTS ON THE STATE OF PREGNANT WOMEN.

It is an accepted fact that with the increase of civilization the diseases incident to pregnancy and parturition also increase; or it may perhaps be more correct to say that with the more civilized nations and with the better classes of society, the dangers and difficulties which beset the pregnant and parturient condition, are more commonly encountered. It is, of course, absurd to argue from this that civilization is an evil. If men and women acted in reasonable accord with the teachings of civilization, and yielded less to vanities and the fascinations of society and of luxurious habits, we would find mothers in general happier, and physically better beings. It is fortunate that the activity of the profession has enabled it to keep fairly pace with the increasing needs of general advance; and that maternity is now largely robbed of its many dolors and evils.

It will be impossible to gauge the amount of misery prevented and relieved by the timely and prudent application to practice, of obstetric and gynaecological teachings. The period of gestation is however, now-a-days, and for that matter has always been, a deal too much permitted to proceed undirected and unhelped throughout its entire duration. Modesty, bashfulness, and such like considerations, very commendable in themselves, are permitted to have unreasonable rule and sway during a very critical and important period of feminine existence. The advice of midwives, incompetent to instruct in the guiding principles, is generally sought, for the alleviation of the many distresses and inconveniences of the parturient condition, while the seeds are being sown of permanent mischief and of danger perhaps to life. A consultation with a medical man, or a specialist if necessary, and the obtaining of competent instructions and adherence thereto will, in a very large percentage of cases, save a mother much distress in the present and in the future. The family physician has it in his power to do much in mitigating and preventing many of the miseries of womanhood. We would therefore commend to careful consideration and for guidance, the rules laid down by Dr. W. B. DEWEES, as to the paramount duties of the obstetrician in the study and care of pregnant women, and as to the moral obligations which must compel the family physician "to promptly do his full duty, by giving adequate instructions concerning the ill effects of improper posture, dress, food, drink, and erroneous habits of living, including the non-forbearance of indiscriminate, excessive and impure sexual indulgences."

These duties are:—

- (1). To discover if the patient be actually pregnant.
- (2). To determine positively if the impregnation be uterine or normal, as contra-distinguished from tubal, abdominal, or abnormal pregnancy.
- (3). To carefully note the pregnant woman's history, including her age, primiparity or multiparity, environments, station in life, general condition of health, period of gestation; as well as her dress, food, drink, and habits of life. To make repeated examinations of the urine and ascertain the temperature from the time pregnancy is established, to the termination of gestation.
- (4). To make a physical examination for the purpose of accurately determining the diameters of the pelvic straits; the symmetry and size of the bony outlet; the integrity, condition and position of the vagina, uterus and other inter-pelvic viscera, and adjacent structures; the state of the abdominal muscles; the presence or absence of hernia, varicose veins, tumors, &c.; the shape, size and condition of the breasts and nipples; the condition of the heart, lungs, mind, stomach, bowels, &c.
- (5). To observe the state of the fœtus, its strength and viability, as well as the implantation of the placenta."

Now if it be essential to the safety and future well-being of the two lives involved, that all these observations should be efficiently made, they must be conducted by, or under the supervision of, duly qualified persons. No reputable obstetrician will gainsay the important bearings of such observations on the progress of gestation, and the safety and consequences of parturition; and in their importance is to be recognised the extent of the moral

obligations of the family physician. The general practitioner will, no doubt, find it both a very delicate and difficult task to carry out these instructions in anything like detail in a case of which he has not been the familiar and regular attendant, but the principles should be kept in view by every medical attendant on a parturient patient, and should be advised or persuasively given effect to as far as possible. The advice indicated in the foregoing rules of Dr. Dawkes are to be tendered as fittingly as possible. This is the duty of the physician who may be consulted in cases of pregnancy, and no considerations should prevent him from doing it. By doing this duty he discharges his moral obligations as far as he is permitted to do, and his patient's reflection on the advice given by him is likely to be followed by her submission and yielding to the professional recommendations. The instructions given in item 3 of the duties of the physician, as laid down by Dr. Dawkes, are perhaps most likely of all others to be submitted to by the parturient female, and most necessary of observance in the majority of cases. We would therefore quote the following rules which it is necessary to insist upon:—

(1). Absolute, regular hours and wholesome environment.

(2). Plain but nutritious and wholesome food and drink, being principally composed of fresh lean meats, fresh fruits, pure milk, and distilled water.

(3). A proper amount of exercise, by walking or light labor on foot, and maintaining the correct erect posture. Whenever infirmity forbids such exercise, recourse should be had to massage, and as much time passed in the open air as is advisable under such unfortunate circumstances. Rest in the recumbent posture after meals and fatiguing efforts, with not less than ten hours' sleep out of every twenty-four.

(4). An open condition of the bowels and skin, which is to be chiefly maintained by proper diet, exercise and bathing, the wearing of flannels, warm low-heeled shoes, and loose garments, and, in rare cases, the proper use of laxatives and hot water enemata.

Analysis of the urine from time to time, and frequent recording of temperature will lead to early recognition, and preventive treatment, of such conditions as dropsy of the lower extremities, oedema of the face and lungs, eclampsia, and even parturial sepsis. Pelvimetry indicated under the fourth head will disclose distorted and contracted conditions, the recognition of which will materially influence both lives, *viz.*, that of the mother and child. We refer to it as Dr. Dawkes departs from traditional teachings, and thinks that the induction of premature labor under such conditions is to be considered a "murderous practice;" and that under these circumstances rational and advanced obstetrics "leaves us to choose principally between but two procedures whenever one finds the pelvis so distorted or contracted that it precludes all possibility of delivering the living child, namely: Sympetomy and Cesarean section." He thinks that the former has but this advantage over the latter, *viz.*, that it is less dangerous to the mother. The mortality of the infants is however less in deliveries by Cesarean

section; and in choosing and deciding between the two operations, Dr. Dawkes would lay down the rule that Symphysectomy should be undertaken only in cases where the conjugate diameter measures at least eight and a half millimeters; and where this measurement is less, Caesarean should be resorted to.

—10—

PRACTICAL POINTS IN TREATING DISEASES OF THE EYE, EAR, NOSE AND THROAT.

As specialism answers far better in a town than it can in a country or district practice, and as the organs of voice, hearing, taste, sight, and smell are so intimately blended that injury to one often reflects heavily on the other, Dr. J. W. PARK tenders a few practical hints for the general practitioner:—(1) The eye should, he thinks, be methodically examined as to: presence or absence of foreign bodies; meridian movability of the eyeballs and of the recti muscles; transparency of the cornea and movability of the iris; and the condition of the conjunctivæ, eyelids, and lachrymal puncta. On the upper or lower lid near the inner canthus and seemingly prodding into the caruncle, you may sometimes find a short inverted white cilium, the removal of which, remedies the entire inflammation. If the pupil is immobile or sluggish, prevent adhesions of the iris to the anterior capsule of the lens and cause dilatation by instilling a mydriatic. Practise thorough antiseptics in all cases, and when examining the cornea, *always* use lid-retractors. If an ulcer is central dilate with *atropin*; but in marginal ring ulcers, which usually start at the sclero-corneal junction contract the pupil with *eserin*. Guard against insufficient or improper food, malhygiene, insanitary habitations, ophthalmia neonatorum, and above all, acute or chronic rhinitis for treatment of the eyes only and neglect of the nose symptoms will not only delay the cure of the patient and aggravate photophobia, but will also conduce to successive return crops of phlyctenular keratitis. Persistent treatment is indicated with *atropin* and yellow oxide of mercury, and nasal douches of boracic acid solution are invaluable when rhinitis accompanies. (2) The ear stands next in importance, and great advance has been made in its surgery as instanced by the removal of the ossicles (but not the stapes generally) and tympanic membrane for chronic suppuration of the middle ear when mastoid complications are absent; but when these are present, the establishment of free drainage by opening up the mastoid process or through the attic of the tympanic cavity and subsequent irrigation with *pyoktanin* will soon cure the patient. The majority of acute or chronic suppurating ears originate from some *pharyngeal or nasal inflammation*. Furuncle of the meatus, though very painful and stubborn in many instances, may often permanently be relieved by a solution of 40 grains of menthol to one ounce of olive oil. (3) The nose answering the place of filter to the lungs has important functions, and damage to it, creates awkward reflex affections of vital parts of the human economy. Therefore thorough cleanliness of the nose should always be insisted on. Stenosis when due to *endothorax*, or *hypertrophy* of the turbinated bones, demands operative interference.

First, petroleum is preferable to alcohol or benzoin as it adheres to the mucous membrane after spraying the most efficient antiseptics for rhinitis with ulcerative conditions and crust formations. Nasal polypi must be removed by the snare, not twisted off. In all cases of ocular or aural disease always examine the nose and treat its conditions. (4). The pharynx and larynx require considerable skill and dexterity for proper examination with the laryngoscope and post-nasal mirrors. In all "mouthbreathers" look for enlarged tonsils, follicular disease and ulcers, hemophilia and adenoid vegetations of the tonsils, or in the vault of the pharynx, and if operation be necessary, use the galvano-cautery preferably and apply chromic acid in conjunction with constitutional treatment; but do not employ the knife, as excision is often really dangerous. Counter-irritants are obnoxious. The pain and dysphagia of acute laryngitis are quickly eased by inhaling menthol through a curved glass inhaler, while the aphonia that sometimes accompanies yields nicely to sprays of alum or sulphocarbonate of zinc in 10-grain solutions. Inhalations of hot steam impregnated with camphor, eucalyptol, terebene, creasote, Tr. benzoin Co. and the direct application of menthol oil or lunar caustic are useful; but it is most important to promote free diaphoresis and expectoration, and to keep the secretions open. Do not trust too much to your patients to carry out your instructions, but attend to things yourself in laryngeal and pharyngeal diseases; and above all, be particularly careful to not forget to look for and treat aural, laryngeal, and nasal complications at the same time.

cost. This reuueoperty to the existence of a purely *Military* Medical Service employed on *Civil* work. The outcome of the system has, we reiterate, been disastrous to the development of medical research and the advancement of medical science, while it has divested independent medical practice and its practitioners of their rights and privileges, by placing a premium on the private services of *State-paid* medical officers.

Our colleges and hospitals are officered by military surgeons to the absolute exclusion of civil practitioners, though they are civil institutions. The field of private practice is monopolized by military surgeons to the positive detriment of their State-paid duties, while they compete with private practitioners on disastrous terms, taking every fee that comes in their way. They are supposed to be consultants, yet they accept family contracts on low fees, they ignore their specialities as professed consultants, and we find a surgical practitioner sitting for three and four hours at night over a midwifery case, while an official obstetric practitioner takes it upon himself to doctor a broken thigh. All this may fit in with LORD CHESTERFIELD'S advice to his son about "making money anyhow," but it positively lowers the prestige of these officers as professed consultants and beggars private physicians, on whose rightful preserves these official monopolists are poaching in every sense of the term.

Then there is the question of the countersignature of the medical certificates of private physicians by official surgeons. This is a cruel injustice, for it puts a false and unjustifiable premium on the State doctor's position, and helps him along in his practice to the detriment of his non-official brother. Besides we have had an instance reported in the *Record* and another recently in the *Reporter* which reveal a very wrong aspect of this ugly question. It places a "whip" in the hands of the official which he can lash about unmercifully at his own sweet whim and fancy to the utter discomfiture of his non-official rival. All this may sound harsh, but criticism of this kind is the only thing that goes through the official hide, which has become adamant in its recklessness to suasion of a milder and more genteel type. But thank the stars! The British medical public has got a clear view of this monopoly business, and the day of retribution and reform begins to dawn. Let all unite in the various medical associations of the country, and let these corporations unite with each other in the combined representation that soon goes before the British Parliament. Let "Patience and Perseverance" be our watch-word, and let persistent and courageous agitation be our policy.

THE DEATH-KNELL OF THE MEDICAL SERVICE ' MONOPOLY IN INDIA.

"THE BRITISH MEDICAL ASSOCIATION. *Reuter's Telegram, London, 1st August 1895.*—DR. ERNEST HART, at the meeting of the British Medical Association, held last night, declared that the whole of the Indian Medical Service needed overhauling and reconstituting. He censured the system whereby officers obtain by mere seniority, high positions for which they are quite incapable. The Association unanimously adopted a Resolution to make representations to the Secretary of State on the utter inadequacy of the sanitary administration of India to give the most elementary protection to Her Majesty's Indian subjects, and to urge the nomination of a Royal Commission or a Departmental Committee of Enquiry."

This glad news has been flashed across sea and land to India, and every son of the soil with every European and Anglo-Indian who has made India his home, will have abundant reason to rejoice. Our heartiest thanks are due to Dr. ERNEST HART, and on behalf of our brethren in India, we offer our cordial appreciation and gratitude to him and to our brethren of the BRITISH MEDICAL ASSOCIATION for their powerful aid in our cause. The cause of scientific medicine and sanitation, the advancement of liberal medical education and every thing that tends to develop and uplift the medical profession as it intimately concerns the people of India, have been utterly stunted, and hampered, and crushed by the weight of a most unjust and arbitrary monopoly, forced upon the country at an exorbitantly unwarrentable

CHOLERA AND LIFE INSURANCE.

DR. ORETEL, the German bacteriologist, who died in Hamburg in September 1894, from "laboratory cholera," had his life insured in favor of his mother. It will be remembered that the doctor contracted the disease in the course of his experiments, but it was never possible to exactly determine the manner of infection either before or after death. The policy read that "the amount was to be payable in case of "violent and sudden accident, independent of the will of the assured, and determined by an external mechanical cause." After the doctor's death the company refused to pay the policy, and the matter was referred to the Hamburg Court of Appeals, which has decided that "the multiplication of the bacilli and the efforts which these produce on the stomach and intestines are to be regarded as a chemical and not a mechanical action."—*Public Health*.

COMMENTS AND NEWS.

AN OLD ANGLO-INDIAN SURGEON.

We quote from the *Anglo-Indian Recorder*:—"Dr. JOHN LEYDEN (B. 1778—D. 1811), the son of a Roxburgh farmer, was born on the banks of the Teviot. He was intended for the Church, but finding that he was not likely to succeed in that calling, studied medicine instead. He took his degree of M.D., and was appointed an Assistant Surgeon in the Hon'ble E. I. Company's service. Arriving in Madras in 1808, he set himself to acquire a knowledge of the vernaculars. He was next posted as Medical Officer to a Commission appointed to survey the newly-acquired territory of Mysore, where his countryman, Sir John Malcolm, was Resident. Subsequently he was transferred to Calcutta, where he held consecutively, the appointments of Hindustani Professor at the College of Fort William, Judge of the 24-Pergunnas, Commissioner of the Court of Requests, and Assay-Master of His Majesty's Mint. In 1811 LEYDEN accompanied Lord Minto in the Expedition against Java, as Surgeon and Interpreter. He died at the early age of 36, of a chill fever brought on, it is supposed, while overhauling some old records in a damp godown in Batavia. Dr. LEYDEN was an eminent linguist, and was the author of several prose works. Among his poetical efforts the best known are *Scenes of Infancy*, and the various pieces contributed to Scott's *Minstrelsy of the Scottish Border*. Two versical tributes to his memory occur to mind; the first, by Sir JOHN MALCOLM, runs as follows:—

Where sleep the brave on Java's strand
Thy ardent spirit, Leyden, fled,
And fame, with cypress shades the land
Where genius fell, and valour bled.
When triumph's tale is westward borne
On Border hills no joy shall gleam,
And thy loved Teviot long shall mourn
The youthful Poet of her stream.

The other is taken from Sir Walter Scott's *Lord of the Isles* (Canto IV).

Scenes sung by him who sings no more;
His bright and brief career is o'er,
And mute his tuneful strains;
Quenched is his lamp of varied lore
That loved the light of song to pour,
A distant and a deadly shore.

Has LEYDEN's cold remains!"

ELEMENTS OF PROFESSIONAL SUCCESS.

SCARCELY a more fitting subject for an address to those entering upon their chosen career in life can be conceived than—"the elements of professional success"—adopted by Dr. W. P. MUNN in addressing the graduating class of the medical department of the University of Denver. Success with some individuals, he pointed out, means only the accumulation of wealth. These are lords of the fee and influences for evil in any community; and the young physician under their influence can never attain to true success. It is the earnest discipline of science, with high ideals, ready to sacrifice mere material interests to the welfare of humanity or the advancement of true scientific attainments, who are tempted to tread the rugged paths leading to true success. The profession, it must be remembered, renders service of value, and ought to receive a proper monetary acknowledgment in return; but money-making should not be the key-note of life. Professional efficiency too must be aimed at; and professional

success does not mean merely scientific study, but also the application of the knowledge so gained to the actual problems of health and disease, for science and practice always in parallel paths. Preventive medicine must be kept in sight as the science of to-day and of the future; and to improve and further this important science one needs, says Dr. MUNN, that talent most essential to real success in science—the talent of application for which the Germans are above all other races remarkable. It is to be remembered too that success comes slowly. One must, moreover, not lose heart at seeing his less competent brethren running up like rockets in professional success. These often come down like sticks. Solid growth is slow. Dr. MUNN's concluding words of advice are that ethical principles should govern one's life, that the confidences of patients should be held inviolate; and that one should ever remember that human life is sacred, and that it is not ours to sanction the destruction of a human entity even from the moment of conception.

THE GOVERNMENT AND THE CERTIFICATES OF PRIVATE PHYSICIANS IN COURTS OF LAW.

OUR readers will remember our contention that the action of the Deputy Police Magistrate of Sealdah in refusing to accept a private physician's medical certificate on the plea that such physician was not a *Presidency Surgeon*, was *ultra vires*, and we now have pleasure in publishing the reply of the Bengal Government to the representation made to it at the time the incident occurred:—

Dated 9th August 1895.

From E. V. LEVINGE, Esq.,

Under-Secretary to the Govt. of Bengal.

To JAMES R. WALLACE, Esq. M.D.,

L.R.C.P. & S. Edin. L.S.A., Lond.

Sir,—With reference to your letter dated the 25th June 1895, preferring a complaint against the action of the Deputy Magistrate, Sealdah, in rejecting a medical certificate given by you to Mr. Croft, who was defendant in a case that was being tried in his Court, I am directed to inform you that no rules have been made by Government regarding the validity of medical certificates in courts of law. The objection which appears to have been taken by the Government Prosecutor of the Sealdah Court that such certificates in a Calcutta Court must be given by a *Presidency Surgeon* does not rest upon the authority of any order passed by Government.

I have the honor to be &c. &c.

E. V. LEVINGE,

Under Secretary to the Government of Bengal.

We can only remind our independent brethren that owing to the absence of any definite law defining and protecting the rights and privileges of independent physicians and surgeons, magistrates and law officials have it in their power to do as they please; though their actions may be illegal, and it therefore behoves all concerned to agitate for the inauguration and establishment of a Medical Act for India.

ORTHOPÆDIC REFORMS.

Two things, says Dr. NOBLE SMITH, of the City Orthopædic Hospital and of All Saints Children's Hospital, are essential to the healthy growth and development of the young, viz. the adoption of natural methods to train the muscles, and the avoidance or removal of counter-acting influences. The neglect of one or both of these considerations, leads to deformities which it is important to recognise and treat at an early stage.

What principally determines the deformities in bones and ligaments is not the extent, but the continuance of an

muscular position. As a matter of fact a position however unsymmetrical and unnatural, does no harm, if it be not continuously maintained, whereas the continuance during rest or exercise, of slightly faulty positions, is harmful. The most potent factor giving rise to deformities in children is the clothing, which in 90 per cent of cases is said to be faulty. The garments should not be tight across the chest. The hips and not the shoulders should support the bottom garments, and hence preference should be given to belts (provided they are not too tight) over braces. Secondly, food insufficient in quantity, indifferent in quality, or badly cooked, leads to weakening of bones and ligaments, and favors deformities. Seeing then the important part that the continuance of a position plays in shaping or altering shapes, the treatment of deformities is best remedied by prolonged rest in a good position; that is, not recumbency *absolutely*, but the avoidance of exercises producing fatigue. Children should rest their backs in sitting down, and should not be made to "sit up." For spinal curvature a child should be fitted with a strong light apparatus, allowing of plenty of light, easy, and continually changing exercise and of free movement in almost every direction to the chest and arms, and enabling the spine to rest completely when necessary.

CHARITABLE DISPENSARIES IN BENGAL.

LAST year (1894) was particularly unhealthy as there was a large prevalence of malarial fever, and the cholera cases rose from 8,077 in the previous year to 12,181, thus showing an increase of 50.8 per cent. Two dispensaries were burnt down and one was closed; but the total number rose from 339 to 383, whose statistics are subjoined:—

| Detail. | 1894. | 1893. | Increase. |
|-----------------------------------|--------------|------------|-----------|
| Total of patients treated ... | 2,285,450 | 1,926,528 | 358,922 |
| Daily (average) attendance ... | 17,689 | 15,426 | 2,263 |
| Ratio per 1,000 of population ... | 32.3 | 27.2 | 5.1 |
| Cholera cases ... | 12,181 | 8,077 | 4,104 |
| Total income of Dispensaries ... | Rs. 7,20,025 | 6,14,737 | 1,05,288 |
| Government Contribution ... | " 76,918 | " 41,434 | 35,484 |
| Expenditure ... | " 6,96,102 | " 5,86,346 | 1,09,756 |
| European Medicines ... | " 1,08,070 | " 80,940 | 27,130 |
| Building charges ... | " 62,026 | " 40,216 | 21,810 |
| Opening Balance for next year ... | " 23,923 | " 28,371 | —4,448 |

While 15 of these dispensaries showed an increase of over 8,000 patients, 5 showed a decline exceeding 2,000, which decrease is accounted for by the general statement that the health of each locality has improved, but the Inspector-General observes that the popularity of a dispensary depends more on the civil surgeon and officers in charge than on the healthiness of the district, and the Lieutenant Governor fully endorses Dr. Ross's pertinent remark "Disease and suffering prevail everywhere, too often, unhappily, on a larger scale than the medical resources available can adequately deal with. But the main difficulty is to induce the people to submit themselves to treatment, and this depends chiefly on the tact and skill of the medical officers concerned and the confidence which the people repose in them: such confidence is a plant of slow growth."

MEDICAL REFORM IN INDIA.

THE *British Medical Journal*, quoting from the *Indian Medical Record*, says:—

"The following are briefly the points to be laid before the Secretary of State for India connected with the Indian Medical Service:

1. The need of putting a stop to military surgeons going into civil employ or duty.

2. To cause all military surgeons now in civil work to revert to military duty.

3. To throw the so-called "expert" or "speaking" posts and leading appointments open to competition in India and in England.

4. To instal the unaccredited as the nucleus for the Indian Civil Medical Service, and to fill up all Civil vacancies from the special additions that will be made to this Service.

5. To utilise military surgeons and assistant surgeons with British and Indian troops under a central organisation, which is tantamount to the amalgamation of the Army Medical and Indian Medical Service.

The *Journal* winds up by adding: "This programme must, in our opinion, sooner or later be adopted."

Our readers will see from our CORRESPONDENCE COLUMNS, that our brethren in Bombay are wide awake and active. We entreat all India to take up their excellent example. In Calcutta the representatives of the INDIAN MEDICAL ASSOCIATION and the MEDICAL ASSOCIATION OF INDIA can easily and becomingly join hands, and our representatives in other provinces ought to take the initiative at once by forming committees and collecting subscriptions. Bombay must not outbeat us in liberality.

ENDOWMENT OF SCIENCE IN JAPAN.

WE quote from the *British Medical Journal*:—"DR. KITASATO is not only the most brilliant scientific investigator in Japan, but one of the most original biologists of the present day of any nation. He worked for many years with KOCH at Berlin; and last year, when the plague was devastating Hong-Kong, he and Dr. AOKANA discovered the bacterial cause of the plague, and were thereby instrumental in arresting its ravages. He has been extremely successful in carrying out the antitoxin treatment of diphtheria, and out of 34 cases treated by him 31 have recovered. He is at present engaged in carrying out a series of experiments on leprosy with the most satisfactory results. If it is a fact that Dr. KITASATO is on the road to discovering not only the cause, but the cure of leprosy, he will confer an immense benefit on a long-suffering section of the human race. Japan has always been celebrated for generously acknowledging the services of her men of genius in art and literature, and it is gratifying to learn that Dr. KITASATO's discoveries are looked upon as contributing to the national glory, and that the Government has unanimously voted him a sum of money to be devoted to the laboratory superintended by him."

Surely this is an object lesson to the Government of India. DR. KITASATO is a native of Japan and not a member of the Indian Medical Service. India can turn out dozens of KITASATOS, but the Government of India has no desire to see them.

A LONDON STORY ABOUT INDIAN BIRTHS TO ORDER.

WE quote from the *British Medical Journal*:—"In India it is customary to entrust the duty of registering births and deaths in outlying country districts to natives, who are generally as ignorant of reading and writing as they are of English. Their memories, unperplexed by knowledge, are, however, retentive, and these registration officers may frequently be seen tramping, in companies of four or five together, into the city, to hand over verbally to the collector the data regarding the births and deaths in their several localities. Suspecting once that the records were carelessly kept in a certain village, a collector reported that the ratio of births was below the average, and suggested to the registrar that his returns could bear improvement. "Ah, it's more births the mahb wants," was the inner thought, and,

with Indian statistics, and expressed the desire to say the thing which pleased, the registrar's returns showed at once a remarkable increase in the number of births. All the babies were duly registered by name, and there was evidence that the village was prospering as population increased. Presently the vaccination officer began to ask why it was that he had no increase of vaccinations, and why these numerous babies were not brought to him? This natural question led to an inquiry, and to the discovery that the children registered so accurately had been born only in the earliest imagination of the registrar, and had been produced in his earnest desire to please the *barra sahib*. "What a story!"

REPORT OF THE BRITISH COMMISSION ON TUBERCULOSIS.

AFTER five long years of careful research and patient experiments, the Commission appointed by the British Parliament to enquire into the relation of food to tuberculosis has reported to the following effect:—(1). The use of meat from tuberculous animals is quite capable of producing the disease in previously healthy animals. (2). A great deal of the flesh of a tuberculous animal can be eaten with impunity, provided the whole of the tuberculous matter was carefully cut away. (3). Milk from the diseased udders of tuberculous cows contains bacilli, and will produce tuberculosis if injected into the blood of a healthy animal, but these conditions do not obtain with the milk drawn from tuberculous cows with healthy udders. (4). The direct inoculation of the flesh of a tuberculous cow does not produce any serious results in a healthy animal. (5). Boiling meat or milk immediately kills the tuberculous bacillus and destroys the toxins, but when meat is roasted, the infectious material on its surface only is killed, while the central or inside portions of the meat are not rendered innocuous. (6). The Commission was not quite agreed as to the value of tuberculin injections as a diagnostic agent in tuberculous cattle, but they admit that it is the most valuable of all the tests hitherto discovered for the detection of tuberculosis.

HOW STRYCHNINE AND COBRA POISON ACT ON THE COBRA.

DR. R. P. BANERJEE of Pachbadra sends us the following note:—

"In March 1908, I went through a series of control experiments with strychnine and cobra venom on different kinds of snakes, said to be poisonous, with the following results:—

- (1) Crotalides (Native of India varieties only) and Viperides were immune to cobra poison.
- (2) Najkies and Bangarides were not immune to viper poison; but immune to crotalidian poison.
- (3) Cobra (in all its varieties) was immune to strychnine.
- (4) Crotalideans were not immune to strychnine.
- (5) Viperides, though easily tetanised by strychnine, were yet safe.
- (6) Yarnides—doubtful.

V. Grieses and V. Hardwickii were immune to cobra and strychnine poison. They are considered by the natives of India more deadly than the cobra. Other species were not immune to any snake poison or strychnine."

CHLOROFORM FATALITIES IN INDIA.

SOME British medical journals have taken up our recent article on this subject and are demanding an inquiry into the facts. It is a fact that fatalities in India during the administration of chloroform are a very rare exception, and we attributed this immunity to the preponderance of Sydenham's principles and refused the comparative frequency of chloro-

form fatalities in England on the same grounds. We would make one small reservation from our previous article. We wrote: "There are almost no chloroform fatalities in India." Our printer omitted the word almost, which made a difference in our view of the case. With this exception, we are prepared to stand by our guns, and we are sure Indian hospital statistics and the practice of independent physicians in this country will bear us out in all we have written. Personally, with a special experience in chloroformisation, we can testify to carefully adhering to SYDENHAM'S principles for the past twenty years in as many as 15,000 cases, without a single casualty approaching dissolution.

INDIAN CURES FOR RABID DOG BITES: PASTEUR ANTIDATED.

DR. R. P. BANERJEE of Pachbadra, writes:—About LALIT KUMAR GUPTA'S article, in your paper of the 1st August 1905, p. 109, *et seq.*,—I have to state that it is the practice in Upper India as well as in cases of mad dog bite, the dog is killed, its ear is pricked and some blood is obtained, and the person bitten has to take this blood with a little powdered black pepper. Again I observed among the Pathans, Beloochees, Brahmis, and Marrees when in South Afghanistan—1882 to 1889—that in cases of dog-bites, instead of the blood of the killed animal, the lower portion of the medulla oblongata (called *kakka*) is taken out and rendered into a pulp, beaten up with rice water, (*conjee*) and the persons bitten are made to drink this morning and evening for three days. It is said to cause one to be immune from rabies. I personally never saw it done, but the general opinion was that this was the only cure at their disposal. This is also suggestive of more experiments in this direction.

LIFE AND DESTINY.

We shape ourselves the joy or fear
Of which the coming life is made.
And fill our future atmosphere
With sunshine or with shade,

The tissues of the life to be
We weave with colours all our own,
And in the field of destiny
We reap as we have sown.

Still shall the soul around it call
The shadows which it gathered here,
And painted on the eternal wall,
The past shall reappear.

Think ye the notes of holy song
On Milton's luteful ear have died?
Think ye that Raphael's angel throng
Has vanished from his side?

Oh no! we live our life again;
Or warmly touched, or coldly dim,
The pictures of the past remain—
Man's works shall follow him.

JOHN G. WHITTIER.

THE JAPANESE MEDICAL SERVICE.

THE Japanese Army is accompanied by 1,350 medical attendants of whom 880 are surgeons. The largest of the military hospitals is at Hiroshima. The staff consists of 30 surgeons and 401 nurses, as well as 178 surgeons and nurses from the Red Cross Society, in which many of the Japanese nobility serve. The society has 188 practitioners and nurses in the field. Dr. KITAZAKI, who has received his medical education in Germany, and was one of the best of Dr. Koch's students, deserves much of the credit for the present condition of surgery, medical practice, and sanitation in Japan.

SUBSCRIPTION FOR CORN

We quote the following poem, from the *New York Medical Journal*—

Prize your corn in the gray of the morn
With a blade that's shaved the dead,
And barefoot go and hide it so
The rain will rust it red:
Dip your foot in the dew and put
A print of it on the floor,
And stow the fat of a brindle cat,
And say this o'er and o'er:
Corney! morny! bladey! dead!
Gorey! sorey! rusty! red!
Footay! putay! floory! stow!
Fatsy! catay!

Mew!

Mew!

Come grease my corn
In the gray of the morn!
Mew! mew! mew!

—JAMES WHITCOMB RILEY.

INSANITARY CALCUTTA.

DR. SIMPSON says that he is not aware of any special causes of a new character tending to render the condition of Calcutta more insanitary than in previous years. The Health Officer remarks, "As regards the pollution of the soil, MR. BALDWIN LATHAM showed that the outfall of the Calcutta sewerage was obstructed by tidal influences, that the sewers were sewers of deposit, that they leaked into the subsoil, and that there was a constant interchange between the sewage, rainfall and subsoil water. That a number of the sewers leak, has been proved by uncovering them for inspection; that the soil is polluted, has been determined by analysis; that the subsoil water is contaminated, has been ascertained by the analysis of the water of wells; so that this condition of affairs produces a sort of *Goragatcha* throughout Calcutta. Since MR. BALDWIN LATHAM'S visit to Calcutta, I have, in every annual report, drawn special attention to the urgency of carrying out his recommendations, and the danger of delay which is now demonstrated from the fact that there were nearly 1,000 more deaths in 1894 from fever than in 1893, and that the increase during the six months of the year has been nearly 900 compared with the corresponding season of last year. The only means, in my opinion, to obviate in an efficient and satisfactory manner this state of affairs, is to take immediate steps to invite an expert of the experience of MR. BALDWIN LATHAM to visit, Calcutta, to draw up the designs for the necessary works, more specially with reference to the outfall of the city, to plan the suburban drainage and set the works in motion under a Superintending Drainage Engineer; and further to appoint this expert as Consulting Engineer, so that he may have complete charge and responsibility of the works, and inspect periodically their progress until they are finished. I believe it is only by reduction of overcrowding by a Building Act and by immediate and radical measures in regard to the purification of the soil, both in the town and suburbs, that it is possible to secure a proper remedy for the present state of things.

It is satisfactory to learn that there have been no cases of typhus fever recorded in Calcutta between 1891 and 1894. Of typhoid fever, there were seven deaths in 1891, four in 1892, eight in 1893, and six in 1894. DR. SIMPSON observes that these numbers refer to mortality and not to sickness; and that if there has been any increase of cases, the disease has not been of a fatal form.

ESSAYS ON LEPROSY.

THE essays on "Leprosy," which obtained the gold and medals offered by the English Leprosy Committee, have been published. These essays relate to the doctrine and antiquities of the disease in the British Islands, its prevalence and decline in Iceland, its increase at the Cape and prevalence in South Africa, its extent and probable causes in Australia, and the conditions under which it prevails in China, Cochinchina, Batavia and the Malay Peninsula.

CALCUTTA FRAUDS AND QUACKS.

Frauds and charlatans spring up in Calcutta like mushrooms. A spectacle seller in Chowringhee declares that he has a cure for cataract, and even advertises pills for purifying the blood, and ointments for sprains, sores and rheumatism. He declares he is an oculist and optician from the London Ophthalmic Hospital. We hereby notify the Police of Calcutta that this statement is a fraud.

WHO IS THIS MIDWIFE?

A so-called European midwife and sick-nurse advertises her need for work in the *Pioneer*. She states that she will not attend Eurasians. This woman has entirely mistaken her calling. Kindliness is an essential quality of a nurse's character, while this woman displays all absence of charity and is positively boorish.

SHORT ITEMS.

The Chemical Examiner to the Government of Bengal having asked all the civil medical officers to send him specimens of the poison of snakes infesting their respective districts, the Civil Surgeon of Howrah has sent ten full-grown black cobras in charge of a snake-charmer.

The *British Medical Association*, headed by Dr. Lawson Tait, protests against any Act of Parliament for registering midwives as "qualified to attend cases of labor." The desire is to make obstetric nurses in every case be under the guidance and control of a doctor.

It now appears that Dr. Allison was fined £20 not for using the titles which the General Medical Council ordered to be erased from the *Register*, but for styling himself L.R.C.P. instead of L.R.C.P. *Edinburgh*. Well, this is a caution!

Assistant Surgeon R. Sharples, I. M. S., is appointed to the sub-medical charge of the detachment of British troops at Lebong near Darjeeling. One hundred men of the Manchester Regiment from Diapora have reached Lebong.

Brigade-Surgeon Lieutenant-Colonel Franklin, Surgeon to the Viceroy, officiates, in addition to his own duties, as Inspector-General of Civil Hospitals in the Punjab, *cum* *habe*, who goes on three months' leave.

How does Franklin manage to doctor the Viceroy and still look after the Punjab? This is a conundrum!

We are glad to note that Surgeon Captain H. J. Dyson, Deputy Sanitary Commissioner, Punjab, has been appointed Sanitary Commissioner of Bengal. We hope the change will turn out to be a good one all round.

The Brussels Medical Graduates' Association held their annual dinner in London on the 29th July. Sir William Foster, M.D., Dr. Glover and Dr. Ernest Hart were among their guests.

Brigade-Surgeon Edward A. Black, M.D., F.R.C.P., who is now practising at Brighton, has sent out another edition of his excellent work on the diseases of children in India.

We are glad to learn that a fund has already been started for annuities in the native hospitals of Bombay, and that certain influential Parsee gentlemen have subscribed.

Brigade-Surgeon Lieutenant-Colonel J. Riddick, late Principal Medical Officer, Base Hospital, Cherat Relief Force, died at Mussoorie on the 27th July.

The index to Vol. VIII—from January to June 1895—of the *Indian Medical Record* goes out with this issue. It is an elaborate production, and hence the delay.

Surgeon-Lieutenant-Colonel J. A. Laing, M.D., Sanitary Commissioner, Madras, retires from the Service on September 9th.

Dr. Robertson, K.C.S.I., rejoins his appointment as British Agent at Chitral at once.

The Commissioners of Darjeeling have arranged to introduce the Pasteur system of filters into their water-works.

The Standard Life Office has scored recently by the generous liberality towards one of its insurers.

Members of the Indian Medical Association, who have not paid their subscriptions, will oblige the Treasurer (Surgeon-Major W. C. Hodgkins, S.A.M., Medical College, Calcutta) by sending them in without delay.

Subscribers in arrears with their payments to the "*Indian Medical Record*" will oblige the Proprietor by remitting their dues as early as possible.

* Returns not complete.

OUR LONDON LETTER.

(From our own Correspondent.)

Some strange facts have come out at recent inquests held in the metropolis. The first is a case of poisoning from habitual chloroform inhalations. **Mr. F. C. BANKS** (*Hæmorrhoids*) *ætat.* 64, had been supplied daily with 2 oz. of chloroform during 18 months. This he inhaled by means of a paper cone sprinkled with m. xxx or more to dull the pain of a poisoned wound of his finger. One morning he was found dead by his wife with one of these cones over his nose. The second, **S. J. RIDGWAY**, *ætat.* 47, habitually applied a cocaine solution to her gums to relieve neuralgic pain. On this particular occasion she was found to be suffering from pain. **DR. CURGENVEN** was summoned and arrived on the scene, but she sank rapidly and died within an hour from cocaine poisoning. It seems that cocaine does appear in the schedule under the sale of Poisons Act, and it has not been ascertained yet what is a toxic dose of this alkaloid.

The fall of Lord Roseberry's cabinet is now *un fait accompli*.

Lord Salisbury has kissed the Queen's hands and accepted his appointment as Prime Minister.

One of our leading biological *savants*, Professor **HUXLEY**, has passed away. He was born at Ealing, 4th May 1825. He entered our profession and was for some years on foreign stations as a naval surgeon and became a professor of Natural History in 1854. He supported powerfully the theories expressed by Darwin's works. He was a lucid and able writer, and is best known to medical men through his small book on "Physiology." His zoological and palæontological works take a high place in scientific literature. Many societies, both at home and abroad, accorded him their highest honors.

The Shahzada seems to have greatly enjoyed his visit to the Houses of Parliament.

The great Indian Exhibition at Earl's Court is now one of "the sights of London;" the novel scene delights the spectators one and all, and is reported an unqualified success.

DR. CORNELIUS HEBZ, the French political refugee, is still resident at Bournemouth, but the English police have withdrawn their supervising official.

The Medical Department of H. M. Queen Victoria costs £2,700 per annum, and comprises 24 individuals! We refer, of course, to her own household.

Many ladies of note, including Lady **RANDOLPH ORTCHILL**, have become ardent "cyclists."

Her Majesty forwarded £3 to a **MRS. GALE**, who has just borne alive two boys and a girl.

The **Duke of CONNAUGHT** presided over the festival dinner in aid of the Westminster Hospital.

The Turkish Government has promulgated an order rendering the notification of certain diseases (cholera, small-pox, dysentery, &c.) compulsory on the practitioners of Constantinople.

At the annual meeting of the Royal Society, 3 distinguished medical men received the much-coveted distinction of F. R. S., their names being **DR. SIDNEY MARTIN**, Professor Maclewan of Glasgow; and **MR. POWER** of the Local Government Board.

We mention with heartfelt regret the death of **MR. ARTHUR DUBAN**, F.R.S., the well-known consulting surgeon of Guy's Hospital; the cause of death was

pneumonia, and the duration of his illness was short. He was a member of the Council of the R. C. S. England, and had been Vice-President. Among his literary efforts are: "The Physiology of Sleep," "Sleeping and Dreaming" together with valuable monographs on surgical and medical subjects.

More deaths are recorded under the heading "Anæsthetics, A. C. E. mixture and Chloroform."

Another eminent medico has left our ranks in the person of **SIR GEORGE BUCHANAN**, M.D., F.R.S. He had lately undergone a seemingly successful operation, and was convalescing. Cardiac pain however suddenly superposed, and he died in a few minutes. He was born in Clarks-well, 1831; educated at University College, where he graduated in 1856. In 1861 he served under the Privy Council and systematized the Vaccination Acts in 1867. In 1869 he became Medical Inspector under the Privy Council, and then went over as assistant M. O. of the Local Government Board. He was appointed Chief to that Board in 1879, retiring in 1892 when he was knighted. He was F. U. L., LL. D. (Edinburgh) F. R. C. P. London.

The registration of milkmen is being talked of in order to check the spread of tuberculosis.

DR. CARL VOGT, the Swiss Naturalist and Physiologist has joined the great majority.

A case of poisoning by "Lysol" comes to us from Austria. Professor **HOFFMANN** stated that the toxic action was due to contained "Creosols" as is the case with commercial and coal tar creosote.

A great loss to physiological science is the decease of **DR. CARL LUDWIG**. For thirty years he taught in the Physiological Institution, Vienna; hither flocked *savants* from all countries to learn his new methods of research and enjoy his genial converse. His work was his greatest delight. Some of the most distinguished physiologists in the world were his pupils, among them were **LAUDER BRUNTON**, **RAY LANKESTER**, **COATES**, &c. At the time of his death he was 78 years of age, and a strong supporter of the Darwinian theory.

DR. H. CHARLTON BASTIAN, F.R.S., has resigned the chair of Medicine at the London University. The vacancy will be worthily filled by **DR. FREDERICK ROBERTS**.

MR. FRANK HAYDON, L.R.C.P., has succeeded **DR. C. E. ARMAND SEMPLE** (deceased) as Secretary to the Court of Examiners, Apothecaries' Hall, London.

Professor **HORSLEY** has successfully trephined a patient for focal epilepsy, and also a woman for traumatic epilepsy. The wound healed by the first intention, and the patient is doing well.

A new method of purifying water has come to the fore from France. Drinking water is treated 1st with permanganate of lime and then filtered by binoxide of manganese. The lime salt in the presence of micro-organisms and organic matter is decomposed into oxygen, oxide of manganese and lime, and to get rid of any excess of lime permanganate, the water is passed over a bed of manganese dioxide. Water thus treated is quite clear and free from organic impurities and bacteria. It certainly is simplicity unadorned as a process.

DR. BINDS states in a therapeutic contemporary that bismuth salicylate is our best substitute for iodoform.

MR. BARNETT operated on a woman *æd.* 22 for that very rare condition known as "Floating Ovary."

Current Medical Literature.

MEDICINE.

Complications of Malaria.

J. M. ANDERS, of Philadelphia, read a paper entitled "A Statistical Study of the Complications of Malaria." He analysed 1,780 cases with reference to their complications, which were noted in 189 instances, or 10.7 per cent. The cases were classified into: intermittent fever, 1,434; remittent, 74; malarial cachexia, 27; chronic malaria and irregular types, 22; unclassified, 222. All instances in which an element of doubt existed were eliminated. The complications of malaria, while as frequent as those of some of the other acute infective diseases, were somewhat peculiar in character, and on the whole not grave in nature, as was illustrated by a list of the complications of most frequent occurrence, prominent among which were heart disease, enteritis, neuralgia, albuminuria, pleurisy, rheumatism, pulmonary tuberculosis, typhoid fever, etc. The author agreed with the opinion that malaria promotes the development of pulmonary tuberculosis. Pleurisy was more frequently due to secondary infection, and was to be regarded as a genuine complication. Rheumatism was a not uncommon concomitant of malarial toxæmia. Among the 1,780 cases of malaria analysed, there were only 5 of lobar pneumonia and 1 of catarrhal pneumonia. There was a class of cases in which both malaria and typhoid fever were met with in the same individual simultaneously. The relationship, however, could not be close, nor was the compound affection due to a third extraneous "compound agent," but to the effects of two pathogenic organisms in one body at the same time. A careful blood examination in cases of suspected typho-malarial fever would shew many to be instances of pure typhoid fever, chills and sweats and intermittent temperature curve being sometimes observed in typhoid. When the temperature curve was of the intermittent type from the commencement, the course of the affection was usually favorable. (*Med. News.*)

Pernicious Anæmia caused by Intestinal Worms.

M. SCHIFFEROVITCH first epitomises as follow the different opinions put forth by various authors in regard to the pathogenesis of this form of anæmia:—

1. Intestinal worms, especially diseased worms, elaborate chemical substances of unknown composition, which poison the organism.
2. Pernicious anæmia may be due to an irritation of the intestinal mucous membrane acting by reflex influence upon the nervous system.
3. The worms absorb the nutritive fluids contained in the intestinal tube, produce reflex depression of the nervous system, and thus render the organism less resistant to attacks of deleterious agents.

The author does not accept the first two statements, but inclines to favor the third theory. He cites in its support two cases which came under his observation. In the first, the patient remained ill, notwithstanding the expulsion of a *botrioccephalus latus*, and the autopsy revealed pathological conditions which explained the origin of the anæmia. In the second case, notable relief was obtained, although no vermifuge had been taken and the worms had not been expelled. In conclusion the author draws attention to the fact that extract of male-fern is not an inoffensive substance, and advises that the dose of 2 to 4 grammes ($\frac{1}{2}$ to 1

drachm) should never be exceeded, and ~~advises the~~ practice of administering it in doses of 10 grammes, as is the custom with certain clinicians.—*Med. Bulletin.*

Recent Cholera Studies.

METSCHNIKOFF declares that:—

1. The well established fact of local immunity against cholera cannot be explained by peculiar conditions restricting the vitality of the specific vibrio.
2. It can not be admitted that local immunity is of the nature of an unrecognised and permanent "vaccination" of the inhabitants.
3. The blood of the inhabitants of immune localities is not distinguishable by any special quality preventive of the cholera infection.
4. The ingestion of cholera cultures does not surely protect against the cholera-producing effect of KOCH's vibrio.
5. The cholera vibrio, developed on nutrient media together with other microbes, is greatly influenced and changed by these.
6. The immunity of animals against intestinal cholera is in great part due to the restrictive influence that the "flora" of the digestive canal exert on the vibrio of cholera.
7. In the immunity and receptivity of human beings and animals against intestinal cholera, the other kinds of microbes in the digestive canal play an important part. This allows one to admit that the vibrio of KOCH (*comma bacillus*) is the specific agent of cholera, and to reconcile this view with the facts of epidemiology—that is, among others, with the influence of time and place on the march of cholera epidemics.—*N. Y. Med. Journ.*

A Sarcoma of Abdominal Cavity cured by Toxins of Erysipelas.

HERMAN MYNTER, M.D., reports a case of an abdominal tumour in a girl of twelve, said to have originated from a fall. Duration of tumour was four months. The enlargement of the abdomen continued, and caused great respiratory distress and œdema of the legs; tapping was tried, but with negative result. It was then decided to make an exploratory incision, when, in addition to two quarts of brown odourless fluid, an inoperable growth was found involving the parietal peritoneum, mesentery, pelvic organs and cæcum. The abdomen was closed and a large tube put in; but before closing it a portion of the growth was removed and proved by microscopical examination to be a sarcoma, consisting chiefly of round and elongated cells with abundant blood-vessels. Four days after operation injections of filtered toxins of erysipelas were commenced, and from that time the tumour began to decrease in size, large pieces of necrotic tissue being continually discharged through the drainage tube. The tumour in this way gradually disappeared, and patient recovered perfect health.—*N. Y. Med. Rec.*

Is Cancer Hereditary?

D. W. ROGER WILLIAMS, writing to the *British Medical Journal*, says:—Perhaps the most direct way of answering such a suggestion as DR. WALTERS's, that "A mother and daughter both suffering from cancer may easily have acquired it from a common source without any special predisposition" is by an appeal to the fact demonstrated by me, that the disease is so often homotopic in its transmission, that is to say, it attacks the corresponding organ in each of the related individuals with preponderating frequency. The following cases illustrate this in a particularly striking manner:

1. A woman, aged 55, came under my observation with uterine cancer, whose maternal grandmother, mother (aged

48), mother's sister, and the patient's two sisters (aged 82 and 84) had all died of cancer of the uterus.

2. In a case recorded by SIBLEY, a mother and her five daughters all died of cancer of the left breast.

3. Of the celebrated BONAPARTE family, NAPOLEON I, his father, his brother LUIGIEN, and two of his sisters all died of cancer of the stomach.

Cases of this kind seem to me to prove conclusively the hereditability of cancer.

Smoker's Vertigo.

M. KOHOS says that vertigo caused by nicotine was very frequently observed, and that it manifested itself sometimes under the form of a slight acute poisoning accompanied with pallor, salivation, cold sweats, headache, vertigo, staggering, etc., which symptoms were produced in those who smoked for the first time; sometimes the poisoning was more serious, as, for instance, in the case of a man who had smoked twenty-five pipes on a wager, who suffered for many months with vertigo. The vertigo of the chronic intoxication from tobacco, he said, might be observed in the workmen and workwomen in tobacco factories, as well as in smokers, in snufftakers, and in those who chewed tobacco. The action of nicotine varied according to the amount absorbed, and the disturbances caused in the life of the cells in consequence of their contact with the poison might also be variable.

M. LE ROY DE MERICOURT remarked that he had never observed smoker's vertigo in Brittany or in certain other countries in which he had lived for a long time, but he had observed a tendency to syncope dependent upon disturbance of the circulation following intoxication with the ordinary tobacco.

Diagnosis of Tuberculosis in Children.

DR. E. WEILL, of Lyons, has observed a special syndrome in three cases of infantile pulmonary tuberculosis which he believes to have been as yet unnoted. It consists in a sensation of cold with perceptible lowering of the peripheral and central temperature, marked cyanosis of the extremities with noticeable modification of the radial pulse, considerable alteration in the number of red cells in the cyanosed portions, and in the composition of the urine. These conditions are readily produced by having the patient leave his bed, and they slowly disappear when he lies down. They are transitory symptoms, of an intermittent character, independent of the clinical form of the tuberculosis, of the stage of the disease, of the season, or of the diet.—*Univ. Med. Journ.*

SURGERY.

The Catheter versus the Hand.

DR. H. STARK has suggested that manual expression of the bladder through the abdominal walls is a procedure that should often supersede catheterism and puncture. Granted a distended bladder and one accessible from the abdomen, Dr. STARK believes the method to be harmless, provided its indication be correctly established. The way in which it is to be carried out is thus described:—"The patient is to lie in bed on his back, with the thighs flexed, so as to attain the maximum relaxation of the abdominal musculature. For the purpose of guarding against eventual formation of folds, the bladder is first lifted up; a concentric and uniform pressure, with the hands flatly placed upon the tumor (the finger-tips being directed toward the symphysis), is exerted in the direction toward the internal urethral orifice. The pressure should not occasion pain, and should not be regarded

as accomplished before the distension of the bladder has completely disappeared." This description seems easy, but we cannot help doubting it to be so. If the method is not to be used when it causes pain, then its applicability must be very limited. Even the moderate distension due to want of opportunity, a condition occasionally experienced by us all, is not unattended with pain, even when manual expression is absent. The contra-indications given by its advocate are these:—1. Where there is occlusion of the urethra. 2. Where there are grave pathological alterations in the vesical wall, when these may threaten laceration. No doubt the passage of a catheter is attended with certain very real dangers, but these can be reduced to a minimum by a careful surgeon.

The Benefit to Ear Patients from Nasal Treatment.

FROM summary observations on this subject, Dr. GRADLE, of Chicago, draws the following conclusions: 1. Acute suppurative inflammation of the middle ear if not treated (locally) has a tendency to become chronic, the tendency increasing with the age of the patient. 2. Chronic suppuration of the middle ear rarely heals without treatment. Neither acute nor chronic purulent otitis is influenced by nasal treatment, but the liability to relapse after their cure is decidedly lessened by the removal of naso-pharyngeal anomalies. 3. Acute catarrh of the middle ear will generally terminate in complete recovery under aural treatment, and sometimes even without it, provided there are no persistent nasal or pharyngeal lesions. But when these are present, the disease is more likely to become chronic in spite of aural treatment, and in many instances can either not be cured, or if improved, will speedily relapse unless the normal state of the nose and throat is restored. 4. Proliferation or adhesive disease of the middle ear is the consequence of retro-nasal catarrh, and its course is determined by the course of the disorder causing it. Aural treatment alone is practically useless in this form of trouble, while nasal treatment, if successful as far as the catarrh is concerned, will also arrest the ear-disease. The restitution of hearing, however, depends on the length of time the disease has lasted, and is often aided by ear-treatment after the cure of the retro-nasal catarrh.—*Journ. of the Amer. Med. Assoc.*

The Conservative Treatment of Muscular Insufficiencies.

HEATH gives the following reasons for a moderately conservative treatment of these cases: 1. The eye muscles are variable in their strength from day to day. 2. Our diagnosis may be wrong. A coincidence may be mistaken for cause and effect, symptoms due to some other cause being attributed to the insufficiency discovered. 3. The difficulty in deciding which is the cause and which the effect in some cases of nervous prostration with insufficiency of one or more eye-muscles. 4. Some patients are neurotic by birth and can never be cured. Palliation is all they can ever expect, and radical treatment becomes hardly justifiable. 5. We should first thoroughly understand the effect of refractive errors and their correction. As errors of refraction frequently cause muscular insufficiencies, correction of the former will often relieve symptoms due to the latter. 6. Regulating the effect of an operation is difficult, if not impossible. It may be too much, too little, or none at all. 7. Results reported by operators are often due to other things than the operation. 8. Some cases shew weakness of all the muscles. 9. Simple measures relieve many cases.—*Annals of Ophthalm. and Otol.*

Surgical Treatment of Empyema.

POINTS IN SURGICAL TREATMENT. Absolute certainty of diagnosis by an exploratory puncture with an aseptic needle; use of a single aspiration in children, followed, in the event of a re-accumulation, by open incision and drainage; no justification for aspiration in adults, except as a mere preliminary to pleurotomy in all recent cases, excluding only the employment of aspiration as an initial procedure in children; avoidance of general anesthesia when practicable; a single opening for drainage, not located in the most dependent portion of the chest; double drainage-tubes to extend but slightly within the cavity; the resection of a small portion of a single rib in case of a fetid discharge or of marked approximation of the ribs; no irrigation of the cavity, unless in the presence of considerable fever, the irrigating solutions to be introduced slowly, of proper temperature, and non-poisonous in nature; observance of scrupulous asepsis during each dressing from the beginning to the end of the case; adoption of multiple rib-resection in the event of an unduly prolonged continuance of the pus-cavity; number of ribs resected and size of section to correspond with the depth and extent of the cavity; exceedingly rare justification for the employment of complete thoracoplasty. (S. G. BOWNEY, *Univ. Med. Jour.*)

Trephining in Epilepsy.

HALLAGER mentions the case of a young woman of neurotic and phthisical family history, *et. 22*. Aphasia developed suddenly in January 1893, the next day convulsions began, and the right upper limb became paretic, then the lower. In the course of a few weeks the aphasia and paresis disappeared, *alicia* supervening. The fit usually began by a trembling sensation in the right arm, which was raised with the wrist bent, the right facial muscles twitched, consciousness was lost, and convulsions set in. Bromide treatment was tried for a year and reduced the frequency of the fits, but had to be abandoned owing to toxic symptoms being set up. In February 1894 memory became impaired and the intellect dulled; there was severe pain on both sides of the head; the right arm also weakened progressively. In April 1894 a trephine hole was made over the centre for the upper limb, and a cyst, the size of a hazelnut found containing a darkish brown fluid. For sometime after the operation the paresis continued, and in May two fits came on; four grains of Bromide were then given with the result that the fits ceased and did not recur up to the time of being last seen in August, 1894.

The Treatment of Goitre.

PROFESSOR KOCHER has had some remarkable results in the treatment of goitre, if we may judge by his report at the Congress of German surgeons, held at Berlin. In the last nine hundred cases operated upon by him, he has abandoned wholly the method of total extirpation and has performed a partial operation only. Since first he acted thus, he has only had one case of cachexia strumipriva, and that in a patient the remaining part of whose thyroid gland was found to be atrophied. This case was cured by the internal administration of thyroid gland. Professor KOCHER's mortality being only twelve per cent, he is well satisfied with his results; but he expressed a hope that the number of operations would soon be reduced and their place taken by internal medication. The most remarkable communication that the professor made, however, was a description of the influence of the internal administration of thyroid extract and phosphate of potassium; and he showed a number of photographs of patients thus treated, in whom the reduction of the gland was very obvious. (*Med. Times and Hosp. Gazette.*)

Sterilization of Catgut.

DR. LATIMER, of Hartford, says that he has found in catgut sold as sterilized, several kinds of bacteria, such as *bacillus subtilis*, *staphylococcus albus*, and *micrococcus tetragenus*. Suppuration, he was sure, often arose from catgut sutures. In thirty-five out of one hundred and forty-nine specimens of catgut he was able to cultivate the bacteria on gelatin. The greatest number of germs were observed in catgut sterilized by a dry process.

OBSTETRICS AND GYNECOLOGY.**Tubal Abortion.**

MURET discusses this subject. The termination of tubal pregnancy during the early months is little recognized, but is nevertheless frequent, and perhaps more frequent than rupture of the gravid tube. Complete tubal abortion takes place all at once. The ovum is expelled into the abdominal cavity with corresponding symptoms more or less marked. Uterine decidua are expelled, and an intraperitoneal hematocoele is formed. Then resolution occurs, and there is no repetition of the onset. Tubal abortion should be considered a favorable termination of tubal pregnancy, not requiring operation and capable of diagnosis. If the abortion be incomplete, part of the ovum is retained in the tube, and a tubal mole is formed. As in incomplete uterine abortion, so with incomplete tubal abortion, hemorrhage occurs repeatedly till the oviduct is evacuated. The blood effused in the tube empties itself into the abdominal cavity through the patent ostium abdominale, and forms a hematocoele which gradually increases. The symptoms of incomplete tubal abortion are tubal colic, the expulsion from the womb of decidua without chorionic villi, and repeated attacks of intermittent pain with symptoms of internal hemorrhage. Locally, there is perceived first a swelling of the tube, and then the development of a gradually enlarging tumour. At first the symptoms of anemia are much less serious and less acute than in the case of rupture of a gravid tube. Sometimes a very considerable thinning of the tubal wall takes place at the summit of the insertion of the tubal mole, and MURET thinks that this may be due to the fact that at first hemorrhage is localised between the ovum and the wall of the tube, and that in this way rupture of the tube might be caused, even though the ostium abdominale were patent. In incomplete tubal abortion abdominal section is always indicated.—B. M. J.

The Permanent Results of Symphysiotomy.

SUFFICIENT time has now elapsed since the wide adoption of symphysiotomy by antiseptic methods to furnish data which will assist in estimating the permanent results of the operation. As most of the patients requiring the operation are dependent on their work for a livelihood, it becomes a serious matter to ascertain the condition of health as regards ability to work, which can be promised to these patients in selecting this operation. The reports from SCHAUTA'S and GUSTAV BRAUN'S clinics by VON WOERNER and RICHARD BRAUN afford data of value upon this question. VON WOERNER reports ten symphysiotomies performed some time previously, most of the patients being still available for observation. Of the 10 patients, 1 died of sepsis after the operation; 6 are in good condition, abundantly able to work without inconvenience; 1 could not be followed after leaving hospital care; 1 cannot stoop to work on her hands and knees without pain in the sacro-femoral joints; 1 suffered from incontinence of urine, which was cured by taking cold baths. BRAUN reports 6 symphysiotomies, and of these none died, 6 are now in good condition, working without inconvenience; 1 suffers from incontinence of urine and sacro-femoral pain on heavy lifting; 1 has incontinence of

THE INDIAN MEDICAL ASSOCIATION.

ESTABLISHED AND REGISTERED 1894.

OFFICE AND LIBRARY:

150, Dharamtala Street, Calcutta.

TERMS OF MEMBERSHIP

Every man or woman, who being duly and legally qualified to practice medicine, by virtue of holding a degree or diploma or qualification in medicine, whether British, Indian, Colonial, European or American, whether from State Institutions or Independent Medical Schools, and every person holding a Government Certificate entitling such person to practice Medicine in any official or private capacity, shall be eligible for election to Membership in the Association.

Every person desirous of becoming a member, shall send an application in the form given below, to the Secretary of the Association, and the Council shall consider and dispose of same at their next meeting. On any person being elected a member, an intimation to the effect shall be notified in the Journal of the Association, and on payment of the subscription, a certificate of membership shall be issued.

Application for Membership.

I, _____, residing at _____, am desirous of being elected a Member of the Indian Medical Association; and I agree to pay the subscription, and to conform to the Rules and Regulations now existing, or which hereafter may be made by virtue of the same.

Name..... Address.....
Professional title..... Date.....

Every Member shall pay a subscription of five rupees per annum which shall entitle him to all the privileges of membership. The subscription shall be considered due in advance on the 1st January of each year, and should be forwarded to the Treasurer.

The *Indian Medical Record* is the Journal of the Association, and is the medium of communication between Members of the Association. In it shall be inserted the Transactions and Proceedings, and all notices of meetings of the Association, and any other business which the Council deem necessary.

The Reading Room and Library of the Association are open to all members of the medical profession from 8 A.M. to 10 P.M. daily (except Sunday.)

Members who have paid their subscription to the Association, may now obtain their membership certificates by applying to the Secretary. Name and address to be plainly written.

Officers and Council:

President:—Lal Madhab Mukerji, Rai Bahadur, L.M.S., F.C.U., Principal, Calcutta Medical School.

Vice-Presidents:—(1) E. W. Chambers, L.M.S., L.S.A., Lond., H. M. Coroner for Calcutta.

(2) H. H. Sir Bhagwat Sinha, K.C.I.E., M.B., C.M., Edin. M.R.C.P., Lond., LL.D., D.C.L., Thakore Sahib of Gondal, Kathiawar.

Members of Council:—Representing Bengal and resident in Calcutta (4 members).

1. H. W. Jones, M.D., M.R.C.S., Eng.

2. Money Lal Dutt, M.R.C.P., Lond.

3. J. G. Anderson, M.R.C.S.

4. K. G. Sircar, M.B., L.R.C.P., Edin.

Representing—

5. **Bombay.**—F. Arthur Foy, M.B., C.M., Edin.

6. **Madras.**—C. G. R. Naylor, M.R.C.S., L.R.C.P., Lond.

7. **Central Provinces.**—Mirza Karim Khan, M.B., C.M., Edin.

8. **Punjab.**—Professor C. C. Caleb, M.B. M.M.

9. **N.W.P. and Oudh.**—John Merton, M.D., L.R.C.P. & S. Edin.

10. **Burma.**—Surgeon-Major Godber, I. M. S.

11. **Independent Native States.**—A. Mitra, Rai Bahadur, L.R.C.P. and S. Edin.

12. **Assam.**—Alf McCabe-Dallas, L.M., Dub., L.K.Q.C.P.I.

Treasurer.—Surgeon-Capt. H. C. Hodgkins, S.A.S., Medical College, Calcutta.

Secretary.—James R. Wallace, M.D., L.R.C.P., L.R.C.S., Edin., Editor, *Indian Medical Record*.

Solicitors.—Messrs. Bignam Robinson, and Sparkes, Attorneys-at-Law, High Court, Calcutta.

Bankers.—Messrs. Girdlehay and Co., Calcutta.

TO THE MEDICAL PROFESSION.

Every practitioner should make it a point to supply himself with a complete set of

SAUNDERS' QUESTION COMPENES,

They are the *latest, best and cheapest* of standard helps. The series comprises no less than twenty-three manuals including every branch of modern Medicine and Surgery, written by the most eminent men of the day, being in accord with the latest views obtainable of the various subjects treated.

and spinning on lifting. In Von Wurm's cases 3 were treated by drilling the symphysis and wiring with silver wire; 12½ the wire suture could not be successfully applied, and 1 had no suture. While good union is possible without suture, yet suture is preferable. BHAUN treated 3 cases with drilling and wiring; with suture of the pericæum, 4; and without suture, 1. There seemed to be no difference in the result in these cases. From these cases the conclusion may be fairly drawn that symphysiotomy under good surgical care is an operation undoubtedly saving fetal life as no serious risk of death or permanent disability to the mother. In view of the excellent results obtained without drilling and wiring the symphysis, this procedure is unnecessary.—*Amer. Journ. of the Med. Sciences.*

Serum treatment of Puerperal Fever and Erysipelas.

M. ROGER related some cases of puerperal fever and erysipelas treated by the injection of an antistreptococcal serum. The first case, a severe one, was cured in forty-eight hours. The next case, treated by himself and CHARBIN, was that of a woman who was delivered on February 16th. The next day fever appeared, and on the evening of February 22nd the temperature was 102.2°F. (39°C.). On the morning of February 23rd the temperature was 101°F. (38.3°C.), lochia fetid; 26 cubic centimetres (6½ fluidrachms) of the serum was injected. In the evening, the temperature having risen nearly one degree, another injection of 20 cubic centimetres (5 fluidrachms) was made. Next morning the patient felt better, and on February 25th, after two more injections of 20 cubic centimetres (5 fluidrachms), the temperature fell. The lochia became normal, and the general condition was excellent. In another instance, a weakly infant, aged 3 weeks, and weighing only about 5½ pounds (2.5 kilogrammes) at its birth, was attacked by erysipelas. Forty-eight hours after the appearance of the rash on the upper lip and cheeks 5 cubic centimetres (1½ fluidrachms) of the serum were injected under the skin. The infant was cured in four days. Its weight rapidly increased, and on March 17th was 6½ pounds 3 (kilogrammes). This case is the more interesting since erysipelas neonatorum is almost always fatal. The last case was one of severe suppurative tonsillitis, with pseudomembrane containing coecol, occurring in a woman twenty hours after confinement. The temperature varied between 108° and 106°F. (40.5° and 41.1°C.); pulse 148 feeble and irregular. The patient received 60 cubic centimetres (1½ fluidounces) of the serum the first day, in two injections; 80 cubic centimetres (1 fluidounce) the next day. Thirty-six hours after the first injection the temperature had dropped to 101°F. (38.3°C.), and twenty-four hours later it became and remained normal. Although these cases are too few in number to justify any general conclusions regarding the curative action of the serum, yet they are believed sufficient to demonstrate its harmlessness and to encourage early resort to the treatment.—*B. M. J.*

The Influence of Tropical Climates on Menstruation.

Dr. JOUBERT, Professor of Midwifery at the Eden Hospital, Calcutta, says:—"It is well known that menstruation appears at an earlier age among the natives of tropical climates than in England, and the impression has been that this was due to the influence of the climate. Dr. JOUBERT has collected statistics on the subject, and he finds that there is very little difference as regards the age at which menstruation appears between Europeans and Europeans born in India, who have lived all their lives in that country. Among the natives, however, menstruation does appear at an earlier age than among Europeans; for instance, of the

cases referred to in Dr. JOUBERT's paper, menarche appeared in girls between twelve and thirteen years of age in 26.4 per cent. of the natives, while it only appeared at this age in 13.4 per cent. of Europeans, and in only 10.4 per cent. of Europeans born and reared in India. According to Dr. JOUBERT the cause of this difference is not to be ascribed to the climate, but to the different social customs prevailing among the natives, and especially to the absence of all privacy in the domestic life of an Indian household, which allows children to become acquainted with sexual matters. Thus, he says, when attending a pregnant or lying-in woman, he has often had to ask that the children of both sexes who were present should be sent away. Indeed, from his knowledge of the country, Dr. JOUBERT says he doubts whether there are any little girls or boys who have reached the age of ten years without having a pretty accurate knowledge of what the sexual relations and child-bearing really mean. We think that Dr. JOUBERT has made out a very probable case for thinking that climate has comparatively little to do with the early appearance of menstruation among the natives in India. It would be interesting to know, however, whether among races living in colder climates, but under similar social conditions as regards want of privacy, &c., a similar precocity as regards the age at which menstruation appears, has been observed.—*Lancet.*

The future Treatment of Septic Pelvic Diseases.

HEUROTIN thinks that in ten years these affections will be treated in a more definite manner than at present. Having failed to stop the disease within the uterus, physicians will not wait idly by whilst peritonitis and cellulitis play havoc and produce incurable destructive conditions. Incipient phlegm in the broad ligaments will be incised and drained early, intratubal disease will be recognised in time for conservative treatment, which will follow the perfection of radical work. In neglected cases, when the appendages are the seat of chronic disease, they will not always be sacrificed; in a young subject drainage of an ovarian or tubal abscess may be followed by cure and restored function. The incision in such a case will be made through the abdominal parietes. But when it is evident that both appendages are hopelessly diseased, hysterectomy through the vagina, with complete removal of the appendages, will be practised. Too many radical operations are now performed; ten years hence conservative treatment will save numerous ovaries. When the appendages are physiologically destroyed the uterus will always be removed with them, and, in default of special contra-indicating reasons, by the way of the vagina.—*Amer. Gyn. and Obst. Journ.*

Therapeutic Action of Chloroform in Parturition.

At the recent meeting of the American Medical Association BEDFORD BROWN read a paper on the use of chloroform in labor. He said that in all literature there are reported not more than 40 cases of death from chloroform in labor. He had used the anæsthetic, given every half hour for from twenty to forty hours, without any trouble following. He had seen profound chloroform narcosis in obstetrics lasting for three or four hours without grave effects. He objected, however, to the careless use of the anæsthetic. The alteration in the vasomotor system of a pregnant woman enabled her to resist the toxic action of chloroform to this wonderful extent. Was the use of chloroform in labor for the relief of pain alone justifiable? He believed it was not only justifiable, but that it would be inhuman to withhold it. At what stage of parturition was chloroform applicable? For pain in

any stage in small quantities. To remove muscular rigidity of the cervix or perineum a larger quantity was required, until there followed complete muscular relaxation. Did chloroform tend to prevent uterine contractions? If given in sufficient quantity it would do this. Did its use tend to promote hemorrhage? He had never seen a greater tendency to hemorrhage after than without its use. In 2,800 cases of labor which he had attended, he had given chloroform in 1,500 without ill effects following. *Medical News.*

—:—

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Intermediary Nerve of Wrisberg.

M. A. CANNIKER remarks that the nerve of Wrisberg has been the subject of much discussion. According to some authors, it was a motor nerve; to others, a sensory nerve. In 1878, M. MATHIAS DUVAL had made out an aberrant branch of the glosso-pharyngeal nerve toward the sensitive centre to which, according to him, the intrabulbar fibres of this nerve were directed. Having made some researches, said M. Cannieu, on the internal ear, he had observed certain facts which enabled him to confirm this interpretation. Thus, among rodents he had ascertained the existence, which had been denied up to that time, of the intermediary nerve of Wrisberg, on the other hand, among bony fishes, he had seen the cellular extensions united in bundles which, he said, should be considered homologous to the intermediary nerve of Wrisberg and as an aberrant branch of the glosso-pharyngeal nerve.—*N. Y. Med. Journal.*

The Anatomy of the Congenital Crescent Downward and Inward.

SALZMANN found that in these cases there is an absence of all signs of distortion of the choroid and of the adjacent inner layers of the sclera. The deep cutting in of the choroid on the side toward the crescent is also absent, as well as the distortion of the nerve-fibre bundles on the side toward the crescent. Throughout the entire region of the crescent there is a doubling in the thickness of the retina, but with partial incomplete development of the two laminae.—*Med. News.*

Primary, Secondary, and Tertiary Retinal Images after Momentary Light Impressions.

BOSSCHA draws the following conclusions from his observations:—

1. The consecutive retinal images appear in the purest and simplest form with the shortest possible illumination of a circumscribed region of the retina, with exclusion of every other source of light.
2. Contrast effects also occur in the vicinity of the retinal image by illumination with the electric spark.
3. The perceptive processes are more distinct when by local retinal irritation a contrast irritation is produced in the surrounding zone.
4. The perception image in its simplest form has three phases:—The primary image, which lasts longer than the illumination itself; the secondary image, which has the complementary color of the first, and is the more distinct the shorter the illumination is; the tertiary image, which has no definite color, and the duration of which increases with that of the illumination.
5. The third phase of the retinal image is distinguished by diminution of the sensitiveness for weak, objective light.
6. The image of a long-continued, homogeneous illumina-

tion is a complex process, composed of the accumulation of a series of light impressions immediately following each other.—*Bulletin of Med.*

Contaminated Ice and Cholera.

WEISS says:—Since the establishment of the relation between epidemics of cholera and water supply, interest has attached to the question whether cholera can be conveyed by ice which has been collected from a contaminated source. It has been many times shown that the cholera vibrio can bear low temperature for several days, and WEISS, as the result of his investigation on this subject, is able to confirm the observations of other workers so far as concerns water. But the cholera vibrio behaves quite differently in the presence of low temperatures when it is in a suitable culture medium. In broth, it remains alive for twenty-one days; in water, which contains much broth, it lives three days longer than in water to which only two drops of broth have been added. In pure dejects kept in the cold, cholera vibrios die sooner than in water, whence it is to be inferred that the vibrios which are present in choleraic discharges also die out in the cold in a few days. Communication of cholera by ice is therefore not to be anticipated, and this agrees completely with the fact that no case has ever yet been observed in which the infection has been carried by ice.—*B. M. J.*

The Parasites of Malaria.

As the result of studying over 600 cases of malarial fever in and about Baltimore, Professor WM. OSLER of the JOHNS HOPKINS University distinguishes three varieties of malarial parasites:—(1) The *Tertian parasite*, requiring about 48 hours for complete development and producing relatively regular tertian paroxysms of from 10 to 12 hours accompanied by heat, chill and sweating, &c. (2) The *Quartan Parasite* requires 72 hours for development and is associated with regular quartan paroxysms; while (3) *Estivo-autumnal parasite*, whose cycle of development has not been definitely determined, varies from 24 to 48 hours, and though its main seat of infection lies in the spleen, bone marrow and internal organs, it is often found in the peripheral circulation and produces fevers varying greatly in nature from quotidian to tertian intermittent fever; but more commonly being a more or less continuous fever, whose paroxysms usually last 24 hours but whose irregular remissions and temperature depend upon the length of the cycle of development and multiple infection of the parasite. Infection with two groups of tertian organisms produces quotidian paroxysms, while multiple groups give rise to irregular, sub-continuous fevers, whereas two group infection of the quartan parasite causes a double quartan fever with two-day paroxysms and third-day remissions: but infection with three groups is associated with daily paroxysms.

The Micro-Organism of Chronic Rheumatism.

SCHULLER has found a specific bacillus for chronic rheumatism. The organisms are described as measuring 3-6 x 0-85 μ , and are constricted at the middle. They stain well with carbol-fuchsin, but are easily decolorized by acids. They are said to grow fast at 25°C. in the dark. All the ordinary culture media are fitted for their development. SCHULLER inoculated the joints of rabbits with cultivations obtained from human joints, and succeeded in producing a non-suppurative arthritis analogous to the rheumatoid arthritis affecting man. Chronic rheumatism seems to be an entirely different disease from the acute form, from which SCHULLER has only succeeded in cultivating staphylococci and streptococci, never the specific bacillus above.—*Brit. Med.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Social Purity Work for Fathers.

We have a great deal to say in our literature about the confidence that should exist between a mother and her daughter, but we ignore altogether too much the frankness that should exist between a father and his son. It is not right to expect that our girls shall bear the whole burden of moral responsibility. Our boys must be taught that the world expects uprightness in a man just as much as it looks for it in a woman. If the men of to-day are protected by an unfair moral discrimination, that is no reason why the men of to-morrow should be so sheltered. If it is for women to elevate their conception of the moral standard for men, it is for the young men of to-day to adjust themselves to that higher measurement. A healthy frankness between the boys of to-day and their fathers is the first step. This is man's part in the aim for social purity. Women must cease condoning actions in men which they will not tolerate in women; men, to whom experience has come, must unfold it to the younger men. It is a favor to a boy that his feelings shall be analyzed for him by his father; that he be taught that his self-control, or his loss of it, means an ascent or a descent in the social scale. There is no harm in a father's pointing out these things to his son; the harm comes when the father neglects to do so. A young man should never be expected in any point of morality to experience what his father can explain and warn him against.—*Good Health.*

Some Hygienic Military Don'ts.

ACCORDING to one of our military journals, the following instructions have been put into the hands of every French soldier proceeding to Madagascar: Never go out without wearing your helmet, not even when the sky is cloudy. When bathing, never lie down on the ground; be content with sitting on your pack. Never go out fasting; never drink anything but boiled water, tea and coffee; never leave off your stomach flannel; never on any account drink alcohol or eat fruit, even though it resembles ours.

Action for Damages for Ruptured Perineum.

PERINEUM asks: "Are there any cases recorded in the law reports in which an action for damages in respect of a ruptured perineum due to alleged negligence has been brought against a medical man, and if so, with what result?"

The editor *B.M.J.* responds:—One such case was heard quite recently before Baron POLLOCK, *DUNKLEY v. LANSLEY*. Drs. CULLINGWORTH and HERMAN gave evidence in favor of the defendant, and the jury, without hearing the speeches of counsel, found that there had been no negligence, and returned a verdict for the defendant.

Sudden Death from Urethral Injection of Cocaine.

In the *Centralblatt für Chirurgie* for March 10, we find an abstract of an account published in *La France Médicale* by M. REOLUS, of a case in which sudden death followed an injection of about six drachms of a five per cent. solution of cocaine into the urethra. The urethral mucous membrane appeared to be quite intact, and the death was attributed to pronounced arterio-sclerosis and to the undue quantity of the drug employed.

In the above case, 15 grains of this drug are used—a dose so large that no excuse can be offered. I have seen syncope follow 3 grains injected in the urethra, and unpleasant symptoms follow 1½ grains; while no systemic symptoms have been in 2-grain injections.

Physicians cannot make disclosures in Actions for Services.

THE New York Code of Civil Procedure provides that a person duly authorized to practise physic or surgery shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity. In an action brought to recover for professional services rendered as a physician and surgeon, after the doctor had testified that he was a physician and surgeon, and as such was called upon by the defendant to treat him, he was asked to state what the defendant said to him about his physical affliction. This was objected to as incompetent and immaterial, upon the ground that the defendant, in making the statements to the witness, made them to a practising physician in his professional capacity, and that they were necessary to enable the physician to act in that capacity, etc. The objection was overruled, and the witness was permitted to answer, giving an account of a secret disease disclosed by the defendant to him which he subsequently treated. But the general term of the Supreme Court holds (*VAN ALLEN v. GORDON*, decided December 27, 1894) that this was an error, and reverses the judgment of the lower court. It says that it can see no escape from the provisions of this section of the code. It does not understand that the defendant had in any manner waived its provisions. He was sued, and was brought into court without his consent and compelled to litigate a claim made against him for services rendered. It might be claimed that he was guilty of a breach of contract in refusing to pay the physician for his services, but that question could only be determined by a trial. If the physician made exorbitant charges, the defendant was not obliged to pay. And the same might be said with reference to the defendant's answer putting in issue the allegations of the complaint. Whether or not he properly interposed his defence could only be determined by the trial. Neither of these acts amounted to a waiver of the statute. Had the defendant himself brought an action against the physician, alleging misconduct or malpractice, he doubtless would be deemed to have waived the statute. But the interposing of a general denial in an action brought against him could not be so treated. It was further urged that if the physician was not permitted to describe the disease with which his patient was afflicted, he could not show the value of his services, and that consequently it could not have been the intention to have the statute apply to a case like this. But the court thinks such a result does not necessarily follow. The physician could still testify to his employment, to the number of visits made, to examinations, prescriptions and operations, and, if the defendant objected to his describing them, the physician might testify as to the value. It might be that it would be impossible to corroborate the physician's testimony as to the value of the services, for the reason that he would not be permitted to disclose to other physicians the character of the services rendered, but the defendant would meet the same embarrassment when he undertook to dispute the value of such services.—*Journ. Am. Med. Assoc.*

THERAPEUTICS AND PHARMACOLOGY. *Sulphenal and Trional.*

SCHAUMANN has investigated the action of these agents on metabolism. Morphine considerably influences metabolism and the nutrition of the patient, and the evil effects of its long-continued use are in no small measure to be attributed to these facts. Chloral hydrate has much the same action on

the tissues. Similar investigations made with sulphonal and trional have hitherto yielded inclusive results. The author has made experiments upon himself. He found that trional had the more marked hypnotic effect. After putting himself on a given diet and producing nitrogenous equilibrium, he was able to show that neither trional nor sulphonal, even in large doses, has any action on metabolism. Hence the superiority of these agents over chloral hydrate, especially when it is considered that the latter also acts on the heart. —*Brit. Med. Journ.*

Lettuce Salad.

PREPARE the lettuce by washing each leaf separately in cold water, rejecting any portion that may be bruised or brown. Drain on a fresh towel or napkin and place in a dish on ice or in some cool place until needed. When ready to use, if the leaves are too large, tear them in pieces with the fingers or a fork (do not cut with a knife), rejecting the large and harder portion of the midrib. Serve with a dressing of strained, stewed tomato and lemon juice, in the proportion of one table-spoonful of lemon juice to one small cup of tomato, with salt to season. A garnish of the chopped or grated yolks of hard boiled eggs makes a pleasing addition.

Oatmeal Cheese.

THIS dish is usually prepared from milk which has curdled from lack of proper care, or from long standing exposed to the air, and which is then to some degree decomposing. But the fact that the curd of milk is coagulated by the use of acids, makes it possible to prepare this dish in a more wholesome manner without waiting for decomposition of the milk. Add to each four quarts of milk one cupful of lemon

juice; let it stand until coagulated, then heat slowly, but do not boil, until the curd has entirely separated from the whey. Turn the whole into a colander lined with a square of clean muslin cloth, and drain off the whey. Add to the curd a little salt and cream, mix all together with a spoon or the hands, and form into cakes or balls for the table. The use of lemon gives a delicious flavor, which may be intensified, if desired, by using a trifle of the grated yellow rind.

Steamed Eggs with Tomato Sauce.

BREAK eggs into individual egg or vegetable dishes, salt very lightly, and place the dishes in a steamer over a kettle of boiling water until the whites are set and a film has formed over the yolk. Serve hot with a dressing of hot stewed tomato which has been rubbed through a strainer to remove seeds and skins.

New Treatment of Diabetes.

AT the last meeting of the Academy of Medicine, DR. A. ROBIN referred to a mode of treating diabetes which he has found successful. For the first period of treatment, which lasts five days, he gives cod-liver oil, alkaline mineral waters, antipyrin, and Solignette's salt. During the second period, occupying fifteen days, he prescribes sulphate of quinine arseniate of soda, alkalies, and 40 centigramme doses of codeine per day. The first five days' medicaments is also continued. Opiates commence a third period of ten days. DR. ROBIN finds belladonna also very useful, while he uses bromide of potassium as an accessory. A fourth period of treatment with tonics has also been tried where the diabetes has been overcome and the patient requires strengthening. DR. ROBIN states that he has obtained twenty-four complete cures out of 100 patients. —*Med. Times and Inop. Gaz.*

Correspondence.

THE CONTROVERSY ON THE ACTION OF STRYCHNINE IN COBRA POISON.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In sending the accompanying communication for publication in your journal, I feel it to be necessary to give you my credentials in order to be allowed to enter in your columns, into the controversy on the strychnine treatment of snake-bites. For more than eleven years I have been engaged in the teaching of Physics, Chemistry and Physiology to students preparing for the University examinations in one or other of the three first-grade Government Colleges in this Presidency. Before entering upon this educational work, I studied Medicine, and have passed the first M.B. and C.M. examination of the Madras University. I have all along been taking some interest in all scientific questions bearing upon the progress of medicine. The subject of the controversy on which I write is one of great importance, and there is an old traditional belief in India that habitual eaters of NUX VOMICA are proof against snake-bite. My object in writing the present article is to evoke a closer and more complete examination of the subject, and I trust you will do me the honour of giving my article as prominent a place as you think it deserves.

Although you have pronounced in your issue of the 18th June 1895 what appears to be your final opinion on the controversy relating to the treatment of snake-bite by strychnine, I cannot believe you have really come

Dr. Elliot states that the last word has been said on the matter. I therefore request you to be kind enough to find space for this commendation in your columns. I think the fact that I do not belong to the medical profession will not in itself be an unimportant consideration in inducing you to comply with my request and to overlook whatever there may be of presumption therein.

Dr. ELLIOT'S experiments on carefully selected animals conducted so well in the Biological Laboratory of the Presidency College here in Madras, have given occasion to this controversy. But the main problem that has to be solved is not whether strychnine acts as an antidote to snake-poison in the case of animals other than man. Dr. MUELLER, the champion of this strychnine treatment of snake-bites, himself says that it does not. Can it then act as an antidote to snake poison in the case of man? This is indeed the crux of the controversy. Obviously there are only two ways of finding an answer to this question: firstly, by means of analogical reasoning from experiments on animals; secondly, by means of clinical observation in cases of snake-bite in man. Before, however, this latter course is allowed to be adopted, it must be well made out that there is not only no intrinsic improbability in the antidotal nature of the proposed treatment, but that physiological and therapeutical considerations point clearly in its favor.

Dr. ELLIOT relies upon the former method of research in the same way in which Dr. MUELLER relies upon the latter; and when doctors differ, it is of course, dangerous for laymen to interfere. Nevertheless, an attempt to give an impartial statement of the position of each of them cannot but be of some value. Dr. MUELLER says that the strychnine treatment of snake-bite has proved positively successful in Australia, and I am not aware if this statement of his has been openly contested and proved to be untrue by means of experiments scientifically conducted for the purpose, in Australia. It is not scientific stily to sneer at this treatment, because it also, like Dr. HALFORD'S ammonia treatment of 25 years ago, hails from Australia, which country can no more be the land of scientific and medical bogies than India or England or any other part of the world. I am sure it is known to all those who take an interest in the subject matter of this controversy that, even before Dr. MUELLER of Australia, certain eminent doctors of the Indian Medical Service had pointed out the probable antagonism existing between strychnine and cobra-poison. Indeed this fact was mentioned recently in some Indian medical journal to prove that Dr. MUELLER is not the discoverer of this antidote to snake-poison. Dr. ELLIOT'S paper, as given in the *Indian Medical Record* of the 1st February 1895, contains a very fair statement of the symptoms of strychninisation as well as of cobra-bite; and students of toxicology will find even in that statement enough to suggest a probable antagonism between the physiological effects of strychnine and cobra-poison. As a matter of fact both Dr. ELLIOT and Dr. MUELLER depend on conclusions based on—analogy. The analogy which Dr. MUELLER relies upon, is that which exists between Indian snakes and Australian snakes, while the analogy that Dr. Elliot rests his arguments upon, is what is to be found between the nervous system

of man and that of the lower vertebrates. Surely the "every kind of analogy" existing between European snakes and Indian snakes must be, while in scientific accordance with "the theory of evolution, the basis of comparative anatomy and physiology," very much stronger than the "every kind of analogy" existing "between the nervous systems of man and the lower vertebrates." Under these circumstances, it is certainly unfair to characterise the strychnine treatment of snake-bites in man as a mere experiment on human lives. On the other hand, there is much in it to justify clinical observation other than in its "empiric" sense as given by Dr. ELLIOT.

It is not wholly right to say, as Dr. MUELLER does, that between the nervous system of man and that of the lower animals there is "only a functional analogy which has been mistaken for a complete identity." It is rather difficult to make out the exact meaning of this statement, but surely even Australian doctors cannot be allowed to defy the truths of comparative anatomy and physiology. We have as yet no such science as comparative therapeutics definitely formulated, and until we acquire it, we cannot be too careful in drawing inferences regarding the effects of drugs on man from their effects on lower animals, particularly when such drugs act directly on the nervous system. There is no doubt that the theory of evolution is largely based on the anatomical and physiological analogy existing between the various progressively classified species of animals. But evolutionary progress also presupposes the gradual development of structural and functional differentiation among them. That such of these variously differentiated conditions of animal life has its own peculiar influence on the therapeutical effects of drugs is well known to all students of scientific medicine, although in many cases very little has been made out as to how and why such influences are produced. Regarding the evidence of poisoning derived from experiments on animals, REES says in his *Manual of Toxicology*—

"The animals best adapted to this purpose are the dog, the cat and the rabbit—especially the former; and in certain cases, the frog. Birds are particularly unsuited for experiments of this sort, since they are affected so very differently from man and the animals just mentioned. The exact sort of information obtained by such experiments seems to be limited to proving the fact of poisoning. We can gather no certain data from them relative to the dose, the rapidity of absorption, the deposition or elimination, in reference to man. We may also, occasionally, learn something of the physiological and pathological action of poisons. The instances of the remarkable discrepancy in the doses of poisonous substances necessary to produce death in men and in lower animals are numerous. Moreover, it should not be forgotten that there are some poisons, derived chiefly from the vegetable kingdom, that prove quite innocuous to certain animals, although very dangerous to men. The rabbit, for example, according to M. RUSON of Berlin, will eat, and thrive upon the leaves of belladonna, hyoscyamus, and stramonium; although on killing the animal the absorbed poisons may be discovered in its body. The goat and sow will eat the leaves and stock of the stramonium with perfect impunity, yet their milk may prove poisonous to those who drink it. One insect, at least, is known that can feed and flourish

as strychnine. The fact is undoubtedly that while certain animals, birds and insects, can eat poisonous plants with impunity, the flesh and secretions of those creatures prove highly poisonous to human beings."

There are instances enough in the above quotation to show that specific modifications in the anatomical and physiological condition of animals have also a modifying influence on the therapeutical effects of poisons; and Dr. ELLIOT himself is not unaware of this important scientific fact. He points out in his valuable paper that the injection of cobra-poison produces in monkeys two additional symptoms which he did not notice in any of the other animals he experimented on, viz., the drooping of the upper eyelids, and what he has described as *drunkenness*. Both these are clearly enough cerebral; why do they appear in monkeys, while being evidently absent in animals of comparatively lower organisation? Have we anything here to do with the fact that in the higher vertebrata the reflex activity of the nerve centres in the spinal cord is largely controlled by the superior influence of the highly developed brain centres? That the spinal cord plays a more important and active part in the physiology of lower animals than in that of man is a fairly well-established conclusion of comparative physiology. This may in a way lead us to an explanation of the characteristically greater sensitiveness of some at least of the lower animals to strychnine. The well-known frog-test for strychnine, proposed by Dr. MARSHALL HALL, may well be taken into consideration here. In this test a frog, if immersed partially for a few minutes in a solution of strychnine containing, according to TAYLOR, even less than $\frac{1}{100000}$ part of a grain, is "suddenly seized with tetanus, and the body and limbs remain rigidly extended." Dr. HARLEY confirms this test, and holds that $\frac{1}{100000}$ of a grain produces the characteristic convulsions. May it not be that this kind of probable relation, existing between the relative importance of the spinal cord in the economy of any of the lower animals and its peculiarly exaggerated sensitiveness to strychnine, has something to do with the failure of the strychnine treatment of snake-bite in them? How this relative importance of the spinal cord in the economy of an animal is related to its position in the biological scale of development has not as yet been well made out by students of comparative physiology. May not the effects of the cobra-poison also on any animal be dependent upon this unascertained relation as those of strychnine seem to be? In regard to questions like these, it is never safe to dogmatise; and in dealing with them it is incumbent on every scientific enquirer to bear in mind that cocksure conclusions are not only inadmissible, but also often misleading. The physiological and anatomical difference of man from the lower mammalia is certainly as much to be taken into account in such discussions as the "every kind of analogy" existing between them.

There is a case of snake-bite reported in the *Indian Medical Gazette* of May 1894, by Surgeon-Captain H. SMITH of the Indian Medical Service, wherein he observes "strychnine seems to have had a controlling influence over the poison of the snake." This is a case which resulted in the death of the patient, and in which the variety of the snake had not been made out; nevertheless the strychnine appeared to relieve the drowsiness,

the comatose condition, and the drooping of the eyelids of the sufferer. How did this happen?

In his reply to Dr. ELLIOT's paper, Dr. MUELLER points out that the action of strychnine on man is rather peculiar in that we have a long well-marked premonitory period that precedes the characteristic dangerous convulsions. This premonitory period with animals is short and scarcely discernible." It may be taken as fairly well established that man is not quite so sensitive to strychnine as the lower animals. Whether the sort of physiological explanation of this, suggested in the previous paragraph, satisfactorily accounts for this, or no, is quite a different matter. "If man were as sensitive to this useful drug," says Dr. MUELLER truly, "many thousands to whom it is prescribed would perish every year." It is no wonder that such differences do exist between the various species of animals in regard to their sensitiveness to particular poisons, especially so if we bear in mind what is known as individual idiosyncrasy relative to the action of drugs on man himself. Dr. MUELLER is certainly wrong when he says that Dr. ELLIOT in his experiments confounds chemical with physiological action in antidotes." He does no such thing. He holds that as a physiological antidote to snake-poison in man, strychnine is worthless, if not harmful, because experiments on animals lower than man have all led to uniformly unsatisfactory results. Do man and the lower animals react alike to strychnine and to cobra poison? In man cobra-poison seems to act as a cerebro-spinal neurotic depressant. In monkeys also it seems to act somewhat similarly, as made out by Dr. ELLIOT himself. It is, however, not at all proved from this, that between the action of cobra-poison on man and on monkeys there is no difference whatsoever; all that we know for certain is that there is, as may well be expected, a closer resemblance between the action of the poison on man and the monkey, than on man and any other lower animal; and in testing the supposed antidotal nature of strychnine to snake-poison solely by means of experiments on monkeys, it has also to be positively proved beforehand that strychnine itself acts alike in every respect both on man and the monkey. In animals lower than the monkey in the scale of biological organisation cobra-poison apparently acts as a spinal neurotic depressant, the cerebral effects, if any, not being marked and noticeable at all. Strychnine is generally known to be a stimulant spinal neurotic poison, but there are cases on record in which it seems to have exercised cerebral effects in man. One such case of snake-bite has already been referred to in this communication. Surgeon-Captain J. C. VAUGHAN of the Indian Medical Service has given another case of snake-bite in the *Indian Medical Gazette* of August 1893, where we have very clear indicatives of strychnine having relieved successfully the head symptoms of a man bitten by a snake. It is therefore certainly doubtful, to say the least of it, whether man and the lower mammalia react fully alike to the two poisons we are considering, and under such circumstances analogical reasoning, from the results of experiments on lower animals, when applied to man, is apt to prove fallacious and inconclusive. It is not at all to be understood from this remark that experiments on animals and inferences from such experiments

are declared to be altogether illegitimate. At best all such experiments have only to be taken as suggestive, and it is needless to mention that even scientific suggestions, as derived, regarding the treatment of diseased conditions in man, require to be verified by clinical observation at the bed-side, of human patients. Until our knowledge of the comparative physiology of the nervous system of animals becomes fuller and sufficiently satisfactory, and until we acquire the knowledge of the much-needed science of comparative therapeutics, it is worse than useless for vivisectionists and biological experimenters to fight against the rational and responsible clinical work of doctors, although their procedure has often, necessarily, to be more or less empirical.

When the spirit of controversy is on, the sweetest of tempers becomes acrimonious, and the clearest of visions partial and imperfect. This is apparently a matter of necessity in the nature of man, quite as much as the other fact that all men are, as if unconsciously, led to think highly of their own achievements. If DR. MUELLER "employs the weapon of abuse" DR. ELLIOT seems to be satisfied with the eloquence of insinuation. These are, however, matters with which no science other than psychology has any immediate concern. Abuse and insinuation apart, we find DR. MUELLER answering DR. ELLIOT thus:—1. The experiments on animals prove almost nothing that has not already been known, regarding the break-down of the nerve-centres of lower animals under the combined strain of snake-poison and strychnine; and as such, they are most uncalled-for. 2. Even from a general point of view, the conclusions drawn from them as affecting man are conclusions from analogy, and cannot be admitted to be final in any scientific enquiry. 3. The results of TSKISTOW's experimental researches are acceptable and instructive in so far as they relate to the elucidation of the several physiological actions of snake-poison. 4. It is proper to expect chemical antidotes of poisons to act exactly alike on all animals, but strychnine is a physiological antidote to snake-poison, and as such acts differently on man and the lower animals. This answer of his is certainly not as full and clear as it might have been, but the position taken in it, is not after all so weak as to be lightly ignored or laughed away.

In your editorial remarks of the 16th June 1895, you refer to the case carefully recorded by Surgeon-Major CADGE and Surgeon-Captain PRATT in the *Indian Medical Gazette* of October 1892; and I request your permission to quote their concluding remarks on that case, here. They say: "We are well aware of the many fallacies surrounding cases of snake-bites, and have neither the wish nor the intention of drawing conclusions from the happy termination of a single isolated case. We have thought it worthy of record for three reasons: Firstly, there is absolutely no doubt that the boy was bitten by a snake. Secondly, because there is absolutely no doubt that the snake was a cobra. We have the identical snake preserved in spirits. In how many cases of so-called cure of snake-bite is there any proof that the offending reptile was really one of the *Thamnophtidia*? And thirdly, because our patient recovered from the effects of the

bite, plus the effects of two-thirds of a grain of strychnine introduced into his system by hypodermic injection. (For a short time it almost appeared as if the patient were about to succumb to the effects of the remedy.) Whether the poisons were in any way antagonistic to each other is another matter. Be this as it may, we shall have no hesitation in trying strychnine again should the opportunity occur."

Here is at least one worthy case for DR. ELLIOT to take into serious consideration. It must, of course, be granted that the over-dose of the antidotal strychnine on a snake-bitten man produces effects positively different from, and more injurious than, 'mere flea-bites' and 'source of amusement.' Yet the recovery from the combined effects of such an over-dose of strychnine and the poison of the cobra must remain inexplicable if the physiological antagonism of the two poisons cannot be believed in. There are also numerous other cases recorded in which decidedly large and poisonous doses of strychnine have not produced their well-known characteristic effects in persons known to be bitten by snakes. How are we to account for the greater tolerance for strychnine exhibited by such persons under such circumstances? It will not do merely to assert in reply that the tolerance of man for strychnine is naturally greater than it has been supposed to be hitherto. To say that strychnine, like brandy and water, only tends, under greater risk to life, to restore people from the depressing effects of fright, usually present in all cases of supposed snake-bite, is an equally untenable position to hold. Both these positions have still to be proved as true; they now rest on no evidence worth mentioning. But one such case as that recorded by DR. CADGE and PRATT is enough to vitiate, to an appreciable extent, all analogical reasoning like that indulged in by DR. ELLIOT; for, as they say, the strength of a chain, is measured by that of its weakest link. However, it is out of the heat of controversy that truth comes out brightened and purified of all its covering of dirty-looking dross. More patience and more charity are imperatively needed among workers in the medical profession, which is undeniably one of the most humane of all professions. Let not truth of any kind be discarded, nor untruth accepted, in the maddening rage of controversy, on insufficient and inconclusive evidence; and all will be well in the end.

It is a pity that DR. BANERJI has been treated with scant courtesy in some quarters, in the course of this controversy.

Yours, &c., M. RANGACHARYA, M.A.
Second Lecturer, Govt. College, Kumbhaknam.
TRIPPLICANE, MADRAS, 5th July 1895.

MEDICAL REFORM IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The movement for medical reform in India for a separation of the Civil and the Military Medical Services, with reconstitution of the civil branch and advancement and proper recognition of its subordinate grades, having enlisted general approval and sympathy, both in India and in England, it has been the feeling of several members of the profession in India and their friends in England that

the time has arrived for a united and sustained effort to secure success to this movement by a thorough organization. The objects the reform aims to attain are, as is now well known, catholic in character, and comprise not only the good of the Indian profession in its various grades, but also the interest and welfare of the public at large and the taxpayer in particular, who would be materially relieved of a considerable portion of the burden of the present military charges.

The reform seeks to throw open to the profession at large, and the Indian profession in particular, the fields and opportunities of scientific work, which have hitherto been denied them. A fair field and no favor to *cast wherever found*, and merit and special training—the only passport to seats of learning and scientific work—are the guiding principles of the proposed reform. It seeks to completely do away with the great evil and mischief now at work in the medical administration of the country, and which is the result of a system which, in the words of Mr. EARNER HAST, is radically wrong, the I. M. S. man being expected by Government to be fit for any post that may be vacant; a system in which men work their way up by seniority to positions for which they are quite incapable.

To compass these ends the reform advocates:—

1. Separation of the Civil from the Military Medical Service of the country, with the formation of one military medical service for India—divided into an European Army branch and a Native Army branch, and in fact the military members of the Indian Medical Service are, at present, under the orders of the head of the European branch medical service, called the Army Medical Service.

2. Re-organization of the Civil Medical Service, reconstituting it as a purely Civil Medical Service, recruited from the open profession of medicine with a due leaning towards the utilisation of indigenous talent, of proved merit and ability, other things being equal.

3. Proper recognition and advancement of the Civil Assistant Surgeons and Hospital Assistants and their absorption into the Civil Medical Service of India.

In order to bring about these results both time and money are required; a sufficiency of funds will secure the desired persistent agitation so necessary to the success of every reform movement. It is proposed to agitate the matter, both in India and in England, by representations in proper quarters, and by sending a delegate to England who would place before the British public, the profession and the authorities, the case of the profession in India, and enlist their sympathy and co-operation in securing the favorable attention thereto of those in power in England. The House of Commons will be appealed to, and it is confidently hoped that it will not be long before some at least, of the reforms set forth above are taken up and carried out.

In order to make the movement thoroughly representative of the Indian profession, Local Committees styled the Bombay, Calcutta, Madras and Lahore, etc., Committees for medical reform in India are being organized and a fund called the Indian Medical Reform Fund has been started. The funds collected by the several Committees will be amalgamated into one general fund, and the same will be utilised to the best advantage towards the objects of the reform as above set forth. The cordial co-operation of all members of the profession is requested, and you will

we trust, assist and advance this movement with your subscription and year assistance.

It is gratifying to notice in the *British Medical Journal* of July 13th, that the organ of the British Medical Association is convinced that our reform programme must sooner or later be adopted. And soon after this we received the glad and reassuring cable message of a warm advocacy of the reform by the British Medical Association at their annual meeting in London on the 1st instant. Such influential support will, no doubt, lighten our work and precipitate action by the authorities. A summary of the whole programme endorsed by the *British Medical Journal* is thus pithily given in its issue of July 13th:—“(1) The need of putting a stop to Military Surgeons going into Civil employ or duty. (2) To cause all Military Surgeons now in Civil work to return to Military duty. (3) To throw the so-called ‘expert’ or ‘specialist’ posts and leading appointments open to competition in India and in England. (4) To instal the Unconvenanted as the nucleus for the Indian Civil Medical Service and to fill up all civil vacancies from the special additions that will be made to this service. 5. To utilize Military Surgeons and Assistant Surgeons with British and Indian troops under a central organisation, which is tantamount to the amalgamation of the Army Medical Staff and Indian Medical Service.”

We give the names of members who have up to date signified their consent to serve on the Committee and subscriptions volunteered at a preliminary meeting held on the 3rd of July last:—

COMMITTEE FOR THE BOMBAY PRESIDENCY.

President.—Dr. Atmaram Pandurang.

Vice-Presidents.—Dr. J. C. Lisboa, Dr. Cowasji Hormusji.

BOMBAY, August 7th 1895.

"THE SECONDING OF MEN IN CIVIL EMPLOY."

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Sometime ago in the remote past, I first heard that the Indian Government had under consideration the idea of seconding all our men who were in "Civil employ." This meant that there would be a promotion made in place of every Medical Warrant Officer, whose services were placed by the Military, at the disposal of the Civil, permanently. Of course, I was prepared to allow that the carrying out of this idea would take some considerable time. From then until now "refreshers" have come across our way, and we have taken heart and looked forward again with hope, to its consummation in the near future. Not long since, i.e., a couple of years ago, I saw something about the same thing in one of the issues of the *Civil and Military Gazette*. For some months I have not seen nor heard anything of this "phantom," and have begun to think lately that it has been thrown out, and will not be carried into effect after all. Sir, have you heard anything of it? Can you give us any hope that the seconding of civil employed men will be carried out at any time, no matter how far off in the distant future? I keep a small copy of the Army List, and study it so far as it concerns us, very carefully.

The study has convinced me that our promotions are slow, much slower than in other departments. Take for instance the first twelve names in the list of first class Assistant Surgeons (over five years service). These men have been in the department since April 1864—perhaps a couple or three of the first from 1863—they have therefore over 31 years' service, and have been Warrant Officers for at least 28 or 29 years. Of this number six men have but a very slender chance of becoming Surgeon-Lieutenants until the latter half of 1897, or the first quarter of 1898, when the youngest of them will have had *thirty-two* years' Warrant Service. What chance have these men of being physically and mentally "fit" to stay on and qualify for the higher pension of Senior Assistant Surgeon, 1st class; considering the worrying and harassing nature of their duties? I say emphatically, for the *majority*, NONE. There are, no doubt, a few with whom time has dealt with a gentle hand, and they have been blessed with a temperament which would allow no cares to distress them out of the ordinary, these few will smile through and keep right side up until the recurrence of that birthday of theirs, which will bring them face to face with the age limit.

There are some who will say there is much to be said on the other side also, and that the members of the Indian Subordinate Medical Department are paid and treated quite as well as they deserve, and that they are a class of mankind who come under the head and class of "dissatisfied." I will not take up very much more of your time or space. I will therefore conclude by giving you an account of an unpleasant experience which occurred to me lately, and it may go some distance to prove that there is something on our side too, which would bear a little looking into.

In the seventies I was a good deal amongst men of the "Ordnance Department"; a few months ago I had some official business to transact in an arsenal, and while there, had to see two men who were quite well known to me. In the seventies they were: one an officiating Magazine Sergeant, the other was permanently in the Department as

a Sergeant with a couple of years' service in it. Now one is a Lieutenant, and the other a Captain. At that time I was 3 years a Warrant Officer. As in duty bound, I made my appearance before each of these and made the usual salute after the most approved fashion in use now, and they returned it listlessly, by raising the right hand a little and pointing the index finger a little upward just as they had seen other officers do to them in the past. They had not been specially promoted, but had taken their regular turn, and though very much behind me at start, had beaten me hollow in the race of life.

The beauty of it was that one of these gentlemen was rather looked upon as a "snob" by those who knew him in the old time, and when I came before him and had to salute him as a superior officer, I certainly felt a sympathy for Joseph's elder brethren, who had to make obeisance to him; only perhaps the brethren in their fear failed to recognize their younger brother, but I knew my man straight off.

Yours, &c. JOB.

20th June 1895.

THE EXTENSION OF FIFTY-FIVE YEARS' RULE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Having perused a letter from "MILES" in your issue of the 1st June 1895, page 422, re the extension of the Fifty-five Years' Rule, by a Government of India Notification, I am of opinion that this new departure will undoubtedly be a block to the Junior Assistant Surgeons of the Indian Subordinate Medical Service, thereby being an injustice to men who have taken the trouble to enter a service, the prospects of which, regards future promotion have only during the last couple of years presented signs of much cream.

There would be no *pique*, if Assistant Surgeons were granted an extension, as long as they were placed on a Supernumerary List, thus causing no bar in the promotion of junior men. As far as their military capacity for active service (a point on which "MILES" lays much stress), I apprehend this question could best be answered by ordering a large number at present nearing the fifties, across the frontiers; but here again we should stay and consider that these men have been our pioneers, and during their younger days had had more hardships, *eg.*, marching and campaigning than those junior in the service, hence if they were allowed an extension, they could with ease and comfort fill up gaps caused by junior men ordered away in the event of war, their services then would be an invaluable aid to the State.

Further, I beg to suggest that the members of the Indian Subordinate Medical Service memorialised Government on this subject, praying that the above-mentioned suggestion be brought into force.

Yours, &c. A. O. M. R.
Bombay**THE MEDICAL CONGRESS ANNIHILATED.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In sending you an extract from the occasional notes published in the columns of *Power of Calcutta* in its issue of the 28th July 1895, I wish to suggest that unless a suitable retaliation is forthcoming, the faith of the

medical faculty to the Congress and its good motives may be mistaken, and also requires you to take such notice as you may think it deserves.

Extract referred to above:—"The Medical Congress, a *farce* put up last year in December, is once more to the front; this time not, however, in the form and manner that it had assumed last year, but in the shape of a *scholarship* report. A novel means has been adopted for its *aim*, quite a *rubbish* as it is. If the outcome of such a *body*, as the whole post of all the leading members of the *leading* art be a report, and a report only, without even an attempt at introducing any salutary measures in the profession or in the sanitary condition of the several municipalities, then it were better if there *would* have been no Congress at all. Nothing short of practical reforms will justify such a gathering, and we have reasons to fear that the members of the faculty, who had travelled long distances to be present at the gathering, were *profoundly* disappointed owing to its nature of business. The *Pioneer* may well advertise the report with its long list of contents, may hawk that a few copies only were available, but there is not a dunce to exchange silver for such trash."

Yours, &c., V. C. RAMALINGA MUDALIAR, L.M.S.

Medical Officer.

MANAMELKUDI, TANJORE DISTRICT 5th August 1895.

(Rather hard hitting, and not altogether suitable.—ED. J. M. E.)

REVIEW.

GUN-SHOT INJURIES: their history, characteristic features, complications and general treatment, with statistics concerning them as they have been met with in warfare: By Surgeon-General SIR T. LONGMORE (Retired), C.B., Q.U.S., F.R.C.S., late Professor of Military Surgery in the Army Medical School, Associate of the Society of Surgery of Paris; Corresponding Member of the Academy of Medicine of France, &c., &c. Second edition, illustrated with 78 wood-cuts. (Publishers, Longmans, Green & Co., London, 1895.) Pages 821. Price 31s. 6d.

This most comprehensive treatise on gun-shot injuries, written by a master, consists of 11 sections and an aggregate of 56 chapters, together with an Appendix of references quoted, with an account of the Geneva Convention of 1864, in which Dr. Longmore took an active part, and a copious index. There are 78 wood-cuts scattered throughout the work, illustrating the letter-press. Dr. LONGMORE says in his *avant-propos* the general plan of his treatise, "that the history of the successive changes which have taken place in the characters of gun-shot injuries since they were first presented in warfare, will not be found in any special chapters on the subject. It is believed that this arrangement will have the advantage of being less formal, and of leading to a clearer understanding of their principal features as they are exhibited at the present day."

The first edition of this great work came out in 1877. After a lapse of 17 years, during which, vast and material changes in weapons, armaments, methods of warfare and Military Hospital organization have taken place, the present (the second) edition has been issued. These changes and advances are fully discussed in the pre-

sent volume, and the information contained in the former edition on many other topics has been revised and brought thoroughly up to date. We consider this work absolutely indispensable as an addition to the bibliographical armamentarium of the military surgeon, and especially to the host of young surgeons aspiring for military service. As a work of reference in times of difficulty, the succinct arrangement of the various chapters renders ready reference to them easy. For this use alone, the treatise stands, to our reckoning, quite unique. The 11 sections present briefly, the following aspects of the subject:—

- Section 1. Gun-shot injuries and how produced.
- " 2. Causes influencing nature, progress, &c., of gun-shot injuries.
- " 3. Signs and distinguishing features of gun-shot injuries.
- " 4. Primary symptoms and complications of gun-shot injuries.
- " 5. Aids to the diagnosis of gun-shot injuries and complications.
- " 6. Occasional complications of gun-shot injuries.
- " 7. Ulterior consequences of gun-shot injuries.
- " 8. General treatment of gun-shot injuries.
- " 9. Arrangements for the care and treatment of wounded soldiers in time of war.
- " 10. Gun-shot injuries in general, nosology, classification, &c.
- " 11. Statistics of gun-shot injuries in warfare.

We can thoroughly recommend the work to all surgeons military or otherwise.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Second grade Mily. Hosp. Asst. Kutubuddin is transferred permanently to Civil Dept. of Burma.

The services of first class Mily. Asst. Surgn. E. P. Clement are placed at disposal of Govt. of N.-P. and Oudh.

First class Hosp. Asst. Kataru Ram, attached to Morwara Battalion, was granted 60 days' leave of absence on full pay, from 28th June.

Priv. leave granted to Surgn.-Maj. J. Crofts, M.D., I.M.S., (Beng.), Med. Officer of Kotah and Jhalawar Agencies, is further extended to 6th August.

Surgn.-Maj. R. J. Baker, M.D., I.M.S. (Bombay), off. Med. Offr. of 2nd Regiment, Central India Horse, and off. Goona Political Agency, is apptd. to office as Med. Offr. 1st Regiment, Central India Horse and of Western Malwa Political Agency, from date of assuming charge and during absence on leave of Surgn.-Capt. T. W. Shaw, M.A.

The undermentioned medical officers have been permitted by the Secretary of State for India to retire from the service, from the dates specified:—Surgn.-Col. Alexander Porter, M.D., I.M.S., Madras Establishment, 10th July; Surgn.-Lieut.-Col. James O'Malley McDonnell, M.D., I.M.S., Bengal Establishment, 29th July.

In continuation of this Office Notification dated the 19th June, 1895, Surgn.-Maj. H. N. V. Hartogson, (Madras), Off. Asst. Surgn. in Meywar, returned to duty on the afternoon of the 23rd July, 1895, from the sick leave granted him in this Office Notification dated the 14th May, 1895, which is hereby extended by four days.

First class Hosp. Asst. Ashgar Ali Khan, attached to the Baluchistan Agency Hosp., held charge of the Chaurahia Disp. and of the Hospitalary Jail, in addition to his own duties, from the 15th June to 6th July, 1895.

The first charge of the Magistrate Jail at Abu was transferred to the charge of the 9th July 1925, from first class Hosp. Asst. Surgn. A. M. Khan, attached to the Rajputana Agency Hosp., to third class Hosp. Asst. Motilal Bhattacharya, in charge of the Charitable Disp.

Surgn. Lieut.-Col. A. Adams, M.D., I. M. S. (Madras) has been appointed to the Western States of Rajputana, and has arrived on the afternoon of the 13th instant, of the privilege leave granted him in this Office Notification, dated the 25th June 1925.

BENGAL GOVERNMENT.

Surgn.-Maj. T. E. Macdonald, Civil Surgn. of Saran, is allowed priv. leave for 90 days, from 28th August.

Asst. Surgn. Kali Prasad Kumar, a superny. at Med. Coll. Hosp., is apptd. to do superny. duty at Presy. Genl. Hosp. until further orders.

The undermentioned Asst. Surgn. having passed prescribed exam., is promoted to grade noted opposite his name :—

Surgn. Das Bhattacharjee, from 2nd grade, promoted to 1st grade; 1st May 1925.

Asst. Surgn. Bhogobutty Kumar Chowdhuri did duty at the Presy. Genl. Hosp. from 21st February to 5th April.

Babu Dino Nath De made over charge of Jalpaiguri Jail to 1st class Asst. Surgn. W. A. Williams on 16th July.

Surgn.-Lieut. Col. F. R. Swaine made over charge of the Ranohi Jail to Surgn.-Lieut. L. Rogers on 10th July.

Surgn.-Capt. F. P. Maynard, Offg. Resident Physician, Med. Coll. Hosp. and Professor of Pathology, Med. Coll., Calcutta, is allowed priv. leave for thirty-seven days from 21st June.

Surgn.-Capt. A. R. S. Anderson is apptd. to act as Professor of Comparative Anatomy and Zoology, Med. Coll., Calcutta, during absence on leave of Surgn.-Capt. A. W. Alcock.

Asst. Surgn. Uma Charan Roy is apptd. to do superny. duty at Med. Coll. Hosp., Calcutta, from 26th July.

Asst. Surgn. Uma Charan Roy, a superny. at Med. Coll. Hosp., is apptd. to have temporary med. charge of sub-division and dispy. at Nator in Rajshahi Dist., during absence, on deputation, of Asst. Surgn. Gunga Gobindo Sarkar.

Asst. Surgn. Hera Lal Dutt, offg. at Nator sub-division and dispy. in Rajshahi dist., is allowed leave for one month and 12 days.

Asst. Surgn. Suresh Chunder Banerjee, a superny. at Med. Coll. Hosp., is apptd. to med. charge of Puri Dispy., vice Asst. Surgn. Syam Nirod Das Gupta, transferred.

Asst. Surgn. Syam Nirod Das Gupta, of Puri Dispy., is apptd. an additional Demonstrator of Anatomy in Med. Coll. Hosp., Calcutta.

Asst. Surgn. Suresh Chandra Bhattacharji, House Surgn. in the 2nd Surgn's Ward of the Med. Coll. Hosp., Calcutta, is apptd. as an additional Demonstrator of Anatomy in that institution until further orders.

Asst. Surgn. Upendra Narayan Roy, offg. at Chapra Dispy. in Saran Dist., is confirmed in that appointment.

Babu Kunja Behari Goswami made over charge of Balasore Jail to Dr. J. L. Hendley on 17th July.

Surgn.-Capt. F. C. Clarkson, Supdt. of Krishnagar Jail, made over charge to Asst. Surgn. Behari Lal Pal on 23rd July.

PUNJAB GOVERNMENT.

Dr. D. N. P. Datta made over charge of duties of Supdt. of Hoshiarpur Jail to Asst.-Surgn. Attar Chand on 1st July.

Surgn.-Capt. G. F. W. Braide, Supdt. of Lahore Central Dist. and Female Jail, has obtained priv. leave of absence for three months, from 3rd July.

Asst. Surgn. J. Davis, Civil Surgn. of Gujranwala, is apptd. to act as Supdt. of Lahore Central Dist. and Female Jail, from 3rd July, vice Surgn.-Capt. G. F. W. Braide, proceeded on leave.

Surgn.-Capt. F. B. Dwyer assumed charge of Civil med. charge of Lahore Dist., on 14th of July, relieving Surgn.-Maj. J. Munroe.

Asst. Surgn. Attar Chand held charge of duties of Supdt. of the Hoshiarpur Jail from 13th to 15th May.

Asst. Surgn. Gobind Ram held charge of duties of Supdt. of Mooltan Dist. Jail, from 22nd to 24th June.

Asst. Surgn. J. Davis made over charge of duties of Supdt. of the Gujranwala Jail to Asst. Surgn. Thakur Datt, Raj Bahadur, on 2nd July.

Surgn.-Lieut. H. J. K. Bantock assumed charge of civil med. duties of Rajapur on 7th of July, relieving Surgn.-Lieut. E. C. MacLeod.

Third class Hosp. Asst. Isa Charr, at present attached to Wazirabad-Lyallpur Railway, having passed Eng. Qualification Exam., is entitled to higher rate of pay of his grade from 12th July.

Third class Hosp. Asst. N. Nabil Bakht, at present attached to Sampla Dispy., Rohtak Dist., having passed Eng. Qualification Exam., is entitled to higher rate of pay of his grade from 18th July.

Third class Hosp. Asst. Laboria Ram, at present attached to Sheikh Budin Dispy., Dera Ismail Khan Dist., having passed English Qualification Exam., is entitled to higher rate of pay of his grade from 6th July.

Third class Hosp. Asst. Jowahir Singh, at present doing general duty at Mooltan, having passed the English Qualification Exam., is entitled to higher rate of pay of grade from 6th July.

Third class Hosp. Asst. Ghulam Nabil, doing general duty at Mayo Hosp., Lahore, to Bauzu for general duty from 29th June.

Third class Hosp. Asst. Ata Muhammad, Tibbi Dispy., Montgomery Dist., has obtained one month's priv. leave from afternoon of 2nd July.

The priv. leave for one month granted to 1st class Hosp. Asst. Abdul Rahman in is converted to leave on med. certificate and extended by four months.

Asst. Surgn. Kali Nath Rai, doing general duty at Mayo Hosp., Lahore, has obtained six months' sick leave on med. certificate from 5th July.

Surgn.-Capt. H. J. Dyson, Deputy Sanitary Commr. in Punjab, has been apptd. Sanitary Commr. of Bengal, and will join his new appointment at end of month.

Krishna Rao, Muhammad Abdul Kudos, D. Muniswami Mudali, M. O. Sundara Sarma, Kunial Raman, Lazar Thambuswami Pillai, Muhammad Khan, M. David Pillai, Mung Shewbo, A. Gopal Rao, B. Vira Bhadrudu.

Primary Exam. for Apothecary, First Class.—G. A. Scully, A. E. Hamlin, F. F. Rath Carreck, Mrs. E. A. Hufiton, A. W. Truter, N. H. Charles, C. J. Bateman.

Second Class.—J. H. L. Westerhout.

Final Exam. for the Apothecary grade, First Class.—Miss N. Ottmann, H. St. Charles Daily, F. P. Viera, F. O. D'Crus, Miss L. Holman.

Second Class.—Miss A. C. Austin.

Exam. for Chemists and Druggists, First Class.—M. Manickam.

The following candidates have passed the Second L.M. and S. Degree Exam. held in July: *First Class*.—Francis Peter, Vleyra, Lawrence Walter, Pereira, Henry St. Charles, Daily. *Second Class*.—K. Thomas Mathew, A. M. Bravym, Andrew Avolino Manuel, Nina Eleanor Ottman, E. A. Veiga, Viraraghava Muttuswami Doss, B. Satyamangalam Kesava Rao, Guanamani Samsou David, S. Sivaramakrishnan, Ooludalur Appalarani Mudali, Palattankal Mathen Mathai, J. Tirusura Manavalaya.

The following is a list of failures in the Second L.M. and S. Degree Exam. held in July:—Surgery and Surgical Anatomy, Ophthalmology, Midwifery and Diseases of Women and Children, Medical Jurisprudence, Operative Surgery, Hygiene, General Pathology.

The following candidates have passed the First L.M. and S. Exam. held in July:—V. P. Subba Aiyar, K. Mathava Menon, T. N. Duraiswami, S. Arunachalam, Edakkunni Rama Wariyar, C. Maria Joseph Sanjivanthan, Richard Jose, V. Trivellore Viraswami Mudali, K. Narasim Jayengar, S. Paramesvaran Pillai, N. Narayana Rao, M. R. Paramesvaran Pillai, Syed Abdus Salam, J. Amritaswami Pillai, Chittoor Kuppuswami Pillai, V. A. Thomas, A. Anthony Moreira, M. Manickam, A. Thomas Thomas.

The following candidates have passed the Preliminary Scientific Exam. held in July:—K. Balasimba Rao, Peter Paul Pinto, C. Bangalore Rama Rao, Pascal Victor Gonsalves, C. V. Nilakanta Aiyar, Maung Ba, Joseph Victor Mascarenhas.

The following candidates have passed the First M.B. and Ch.M. Exam. held in July:—M. Krishnaswami, Lawrence Dudley Parsons, Alfred Spittelen, G. Asirvadam Pillai, Kurien, Eapen.

Surgn.-Capt. Robert Henry Elliot, F.R.C.S. (England), M.S., M.S. (London), to act as Superintendent, Ophthalmic Hosp., Madras, during absence of Surgn.-Maj. T. H. Pope, M.D., on leave, or until further orders, and without prejudice to his present duties as Professor of Biology, Presidency Coll., Madras, until relieved by Mr. A. G. Bourne.

Civil Apothecary V. Venkates, Acting Asst. to Dist. Med. and Sanitary Officer, Kuzhool, granted priv. leave for 15 days.

BOMBAY GOVERNMENT.

The following transfers are sanctioned:—*Asst. Surgs.*
Indian Subordinate Med. Dept. Daniel William Adolphus Gillespie, 2nd class, 1st grade, from Mil. Dept. to Civil Dept. and attached to Civil Hosp., Barisal.

Hosp. Asst. Yeshwant Gaisooji, 3rd class, from genl. duty, Nashik, up to 2nd June, to cholera duty, Malegaon City, from 2nd June, chargeable to Municipal Fund.

Hosp. Asst. Yeshwant Gaisooji, 3rd class, from cholera duty Malegaon City, up to 18th June to genl. duty, Nashik, from 18th June.

Hosp. Asst. V. Appadorai Nalkar, 3rd class, from genl. duty, Sholapur, up to 4th July, to fair duty, Pandharpur (Barsi Road), from 4th July, chargeable to Pandharpur Municipality.

Hosp. Asst. Appadorai Nalkar, 3rd class, from fair duty, Pandharpur (Barsi Road), up to 12th July, chargeable to Pandharpur Municipality, to genl. duty, Sholapur, from 13th July.

Hosp. Asst. Rajaram Shivaram, 3rd class, from genl. duty, Sholapur, up to 4th July, to fair duty, Pandharpur (Mohol), from 4th July, chargeable to Pandharpur Municipality.

Hosp. Asst. Rajaram Shivaram, 3rd class, from fair duty, Pandharpur (Mohol), up to 12th July chargeable to Pandharpur Municipality, to genl. duty, Sholapur, from 13th July.

Hosp. Asst. Kundamul Karamchand, 3rd class, from N.-W. Railway Dispy., Laki, up to 31st May, to N.-W. Railway Hosp. Kotri, from 1st June.

Hosp. Asst. Mulchand Jamatmal, 3rd class from N.-W. Railway Hosp., Kotri, up to 1st June to N.-W. Railway Dispy. Laki, from 1st June.

Hosp. Asst. Mulchand Jamatmal, 3rd class, from N.-W. Railway Dispy., Laki, up to 22nd June to N.-W. Railway Dispy., Ruk, from 28th June.

Hosp. Asst. Akhund Salleh Mahomed, 3rd class, from N.-W. Railway Dispy., Ruk, up to 28th June to N.-W. Railway Dispy., Laki, from 30th June.

The undermentioned are allowed leave:—

The priv. leave therein granted to 2nd class Hosp. Asst. Permanand Vishandas is converted into furlough for one year from 2nd January.

Third class Hosp. Asst. Govind Gungadhar was on fair duty, Shingnapur, Satara Collectorate, from 30th March to 13th April.

Third class Hosp. Asst. Krishnaji Ramchander, was on fair duty, Sangam, Hungund Taluka, Bijapur Collectorate, from 3rd April to 31st May.

Third class Hosp. Asst. Bhimaji Krishna, was on fair duty, Golgeri Sindi Taluka, Bijapur Collectorate, from 2nd April to 20th April.

Against the name of 3rd class Hosp. Asst. Samaldas Nanji, for 4th June read 4th June.

Against the name of 3rd grade Hosp. Asst. Viragoo Dhurmalangam, for 27th July read 24th July.

Asst. Surgn. J. E. Bocarro, L.M.S., has been apptd. Asst. to Med. Offr. Kathiawar Political Agency, and in charge West Hosp. Rajkot, from 7th July *vice* Asst. Surgn. Krachi Shariarji Bharucha, L.M.S., transferred to Poona.

Surgn.-Lieut. D. C. Johnston is apptd. to act as Civil Surgn. Jacobabad, in addition to his own duties from 4th June.

Surgn.-Maj. Danjisha Navroji Parakh, to be Surgn.-Lieut.-Col.

Surgn.-Capt. W. H. Burke, Surgn.-Capt. J. Crimmin, to be Surgn.-Maj.

Surgn.-Lieut. W. C. Sprague to be Surgn.-Capt. Senior Assistant Surgn. and Honorary Surgn.-Lieut. J. Gallagher to be Honorary Surgn.-Capt.

Kalkhoru Sorabji Engineer A. D. Roberts, to be Asst. Surgn., 1st grade.

Shas Gobind, Sorabji Fardunji Ghamlihi, Venkatesh Balvant Karandhar, J. H. Wittenbury, to Asst. Surgn., 2nd grade.

CENTRAL PROVINCES GOVERNMENT.

Surgn.-Maj. C. Henderson, Civil Surgn., returned from priv. leave and resumed executive and med. charge of Hoshangabad Jail from Asst. Surgn. Mrigendra Lal Mitra on 20th instant.

Second class Civil Hosp. Asst. Surji Rao, doing duty under orders of Civil Surgn., Saugor, is directed to do duty under orders of Civil Surgn., Narsingpur.

Second class Civil Hosp. Asst. Partab Singh, doing duty under orders of Civil Surgn., Sambalpur, is apptd. to Jail Hosp., Saugor.

On being relieved by Civil Hosp. Asst. Partab Singh, 3rd class Civil Hosp. Asst. Ramkrishna Lal, temply attached to Jail Hosp., Saugor, is directed to do duty under orders of Civil, Surgn. Saugor.

Priv. leave for fourteen days was granted to 3rd class Civil Hosp. Asst. Nand Kishore, attached to Jail and Police Hosp., Betul, from 1st to 14th July.

N.-W. P. AND OUDH GOVERNMENT.

The undermentioned passed students of Lahore Med. Coll. are apptd. to Civil Med. Dept. of these Provinces as 3rd grade Asst. Surgns. from dates mentioned against their names, and are placed on reserve duty at Lucknow:—Shashi Bhushan Banerji, 10th June; Bishambhar Sahay, 10th July.

The services of undermentioned med. offrs. of Bengal Estab. are placed permanently at disposal of Govt. of N.-W. P. and Oudh from dates on which they may be respectively confirmed in civil employ by that Govt.:—Surgn.-Capt. C. C. Manifold, Surgn.-Maj. G. M. J. Giles, M.B., F.R.C.S., Surgn.-Capt. J. M. Crawford, M.B., C.M.

Surgn.-Capt. L. E. Anderson, A.M.S., to the civil med. charge of Muttra Dist., in addition to his other duties, from 27th June.

Surgn.-Capt. G. H. Fink's, services have been replaced at disposal of Govt. of India.

Surgn.-Capt. C. C. Manifold, at present employed in Rampur State, whose services have been placed permanently at disposal of this Govt. by Govt. of India, Home Dept., to be Civil Surgn., 2nd class, and to be seconded in that class.

Surgn.-Maj. G. M. J. Giles, Offg. Civil Surgn., to be Civil Surgn., 2nd class, with grade station Jhansi, from 8th May 1895, *vice* Surgn.-Maj. Deane, deceased.

Surgn.-Capt. J. M. Crawford, Offg. Civil Surgn., to be Civil Surgn., 2nd class, with grade station Azamgarh, but to continue to offic. as Supdt. Central Prison, Benares.

The services of first class Mil. Asst. Surgn. E. P. Clement are placed at disposal of Govt. of N.-W. P. and Oudh.

Asst. Surgn. Ikhtdaruddin, from charge of Sadr Dispy., Hardoi, to that of Sandila Branch Dispy. in same dist.

Asst. Surgn. Surash Chandra Ghose, from charge of Sandila Branch Dispy. in Hardoi Dist. to that of Sadr Dispy. in that dist.

BURMA GOVERNMENT.

Surgn.-Maj. R. E. S. Davis, M.B., made over, and Surgn.-Lieut.-Col. O. Baker assumed, charge of duties of Junior Civil Surgn. and Superintendent, Lunatic Asylum, Rangoon, on 13th July.

On abolition of Civil Surgeoncy of Shwegyin Dist., Senior Asst. Surgeon Henry Wells relinquished charge of duties on 9th July.

First class Asst. Surgn. John Fisher made over, and Senior Asst. Surgn. Henry Wells assumed, charge of duties of Civil Surgeon, Prome, on 18th July.

First grade Hosp. Asst. Abdul Rashid, on availing himself of priv. leave for one month, relinquished charge at Civil Hosp. Yandoon, Thongwa Dist., on 1st July.

Second grade Hosp. Asst. Ramaya Nagappa, on re-transfer to Mil. duties, relinquished charge at Outpost Hosp. Mingin, Upper Chindwin Dist., on 24th June.

Second grade Hosp. Asst. D. P. DeSouza relinquished charge at Police Hosp., Bhamo, on 18th June, and assumed charge at Civil Dispy., Yandoon, Thongwa Dist., on 1st July.

Third grade Hosp. Asst., Wazir Singh relinquished charge at the Civil Hosp., Kindat, Upper Chindwin Dist., on 30th June, and assumed charge at Outpost Hosp., Paungbyin, Upper Chindwin Dist., on 27th June.

Third grade Hosp. Asst. Mahomed Hussain relinquished charge at Outpost Hosp., Kazi, Myitkyina Dist., on 24th June, and assumed charge at Police Hosp., Myitkyina, on 27th June.

Third grade Hosp. Asst. Shaik Abdool Majid assumed charge at Outpost Hosp., Mingin, Upper Chindwin Dist., on 24th June.

Third grade Hosp. Asst. Poromanand Mohapatra assumed, as an additional duty, charge of Jail Hosp., Kindat, Upper Chindwin Dist., on 10th June, *vice* 2nd grade Hosp. Asst., Abraham Samuel.

Third grade Hosp. Asst. Anantharam Krishna Pillay assumed as an additional duty charge of Police Hosp., Shwebo, on 4th July, *vice* 3rd grade Hosp. Asst., Sletoo Mohan Bose.

Third grade Hosp. Asst. Pyidath Appa assumed charge at Outpost Hosp., Myittha, Kyaikse Dist., on 7th July.

ASSAM GOVERNMENT.

Third grade Hosp. Asst. Chandra Kisor Sen, is med. charge of Jalaguti Disp., in Nowgong Dist., is transferred to Khasi and Jaintia Hills Dist., and is apptd. to med. charge of Shalla Disp. in that Dist. from 8th July.

Third grade Hosp. Asst. Javar Chandra Karmakar, in med. charge of Shalla Disp. in Khasi and Jaintia Hills Dist., is transferred to Nowgong Dist., and is apptd. a superny. under orders of Civil Med. Offr. of that dist., from 19th July.

Sick leave for two months is granted to 3rd grade Hosp. Asst. Binaya Charan Ghosal, in extension of sick leave granted to him in Med. Dept., 4th July.

Masud Nasir Ali, a passed student of Patna Temple School of Medicine, is apptd. on probation for six months a Civil Hosp. Asst. in Assam, and is posted to Sylhet for duty as a superny. from 26th July.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

CREE.—On July 26th, at Kasmall, the wife of Surgn.-Capt. H. E. Cree, Army Medical Staff, of a daughter.

CARTER.—At Scarborough, on the 3rd July, the wife of Deputy Surgn.-Gen. H. Vandyke Carter, M.D., Q.M.S., of a daughter.

MARRIAGE.

SEXTON—CONWAY.—At the Roman Catholic Church, Chakrata, on the 31st July, 1895, Michael John Sexton, Surgn.-Capt., M.D., A.M.S., to Catherine (Katie), eldest daughter of Capt. John Conway, the Duke of Cornwall's Light Infantry.

DEATH.

GLADWIN.—At Lucknow, on the 5th August, 1895, Charles Gladwin, son of the late Major Francis Ulric Gladwin, 13th B. N. I., aged 81 years and 9 months. Deeply regretted.

NOTICES TO CORRESPONDENTS.

R. B. (Baluchistan).—Possessed of an Indian degree (M.D., M.B., or L. M. S.) you can obtain the Edinburgh M. B. and C. M. degrees with a year's residence and examination. With the same Indian degrees you can obtain any British Corporation diploma (such as the Surgeons, Physicians and Apothecaries diploma), by simply appearing for the senior examination of these bodies. A complete Indian University curriculum meets every requirement of the Corporations and Universities of Great Britain.

P. A. W. (Bernardino).—No change has been made in the subscription to the *Record* or the Association. The scheme fell through.

L. P. C. (Kohina).—The form of intending members for the Indian Medical Association to fill up, is to be found in each issue of the *Record*, vide advertisements.

S. N. G. (Jalapaahar).—Will you kindly prepare the petition and fill in the regulations and quotations from rules &c., which support your prayer, and we will without further delay arrange to have the memorial sent in. The original papers cannot be found.

P. K. M. (Jagati).—Apply to the Manager for a copy of Saunders' book on Diseases of Children.

U. P. D. (Warda, C. P.).—All information concerning the Association will be found in the *Record*. Fill in the form (written) and send it to this office. See the Business Notices of the *Record* for information regarding subscription, &c.

H. B. (Maulkango).—The index goes out this issue.

H. C. M. (Patna).—You will find all the information you need regarding Indian and British Medical Colleges in the *Medical Register and Directory of the Indian Empire* to be had of the Manager of this office.

F. G. (Darjeeling).—Yes, the appointment ought to result in the officer named being seconded.

L. M. Kadir, C. M. S., of Jalandhar writes to say he has found bandage in small doses frequently, very useful in various menorrhagia.

V. S. B. M. (Charnagiri).—The stationery suggested by the Manager of this Office has been specially got up for members of the Indian Medical Association and for members of the Military Assistant Surgeon service. Each have a neat crest of their own and are light and good, a sheet of paper and envelope being carried by a half anna stamp. The general use of one kind of paper and crest will it is hoped, lead to the formation of a proper *esprit de corps*.

G. E. K. (Bolarum).—The fund you write about will soon be formed; the scheme is under discussion.

J. S. H. (Nowgong).—Saunders' books will be found perfectly suitable to Indian examinations.

A. B. (Southampton).—Your paper is very interesting reading, but is somewhat late in the day. We have sent it to a local paper in the hope that it will be used.

H. D. (Darjeeling).—Saunders' Series on Gynecology will quite suit you.

Other contributors and correspondents will kindly have patience with us. Their papers will appear as early as practicable. Press of work prevents our noticing them in detail.

ORIGINAL ARTICLES.

REMARKS ON THE SALE OF POISONS AND OF QUACKS AND QUACKERY IN INDIA.

By Surgeon-Capt. PATRICK HENRI, M.D., F.R.S.E., F.R.C.S., D.P.H. (Cantab).

Lecturer on Pathology and Clinical Medicine, His Highness the Nizam's Medical School, Hyderabad.

THE absence of definite restrictive measures against the sale of poisons has been felt throughout this country by those having the interest of the people at heart, that we cannot go on *in perpetuo* without legislating upon this very vital question. Recently I drew up a scheme to meet the needs of the Municipal area, of which I am Health Officer, and as there must be many places in India which might to some small extent be benefited by knowing what has been attempted in this place, I submit my views:—

1. It has frequently been my duty to represent the urgent necessity for introducing restrictive measures in regard to the sale of poisons in these dominions, and especially within the limits of this Municipality with which I have special concern, as its Health Officer. In these representations, I have called attention to the appalling danger to the population, and the serious premium on criminal poisoning, arising out of the unhampered and unrestricted sale of lethal drugs. The objection that in "any country where poisonous drugs are habitually consumed by the people in prodigious quantities, it would be difficult to exercise any limitation upon the sale of poisons," is purely theoretical, and one which could readily be met by a qualifying clause in any enactment or resolution of the sale of poisons. It is notorious that in almost all parts of India any person can purchase for a few pice a sufficient quantity of any poisonous drug as arsenic, *koochla* (nux vomica) or strychnine, *dhatura*, &c., to destroy a number of human lives. The results of analyses by Government Chemical Analysts all over the country shew that in a large percentage of the cases arsenic is used as a homicidal poison, as well as in the poisoning of cattle, either from malice to cattle owners, or by chucklers,* for the sake of the hides of the animals so poisoned. Strychnine is occasionally homicidally used, and *dhatura* seed is frequently given in curry, or in confectionery, to intoxicate or hocus people and then rob or kill them.

2. It is reasonable to suppose that a certain amount of poisoning, both homicidal and suicidal, goes on in our Municipality, unless we arrive at the illogical conclusion, that the people of these parts, who live under precisely the same moral, social, and domestic conditions as do those of any other town or city in this large empire, are conspicuous as the only community in India in which this form of crime is not met with. For with the unusual facilities afforded in *seranams*, the privacy of which is so stringently maintained, it would be remarkable indeed were such not the case. I cannot personally state it as a fact, but, reasoning comparatively, it is quite possible that a certain amount of secret poisoning, analogous to

the criminal abortion of which we hear so much, is carried on here as in other parts of India, as the list of deaths by poison is only the list of the fatal cases that are detected.

(3). But here is a cause of death which, from the very surroundings of *serana* life, is peculiarly liable to remain undiscovered, as all the pawns of the murderous and criminal poisoner are naturally based on the endeavour not to be detected. On the other hand, the accidental poisoner, the careless physician who in prescribing a drug writes "drachms" instead of "grains" the negligent dispenser who mistakes strychnine for opium salts or oxalic acid (a mistake which has often been made,) or any other poisonous drug for a harmless one, is at first not aware of the grave error he has made, and neither he nor any one else may ever be enlightened upon this point. Indeed, it may so happen that unless the poison be such a one as to make a decided impression on the mouth or palate, the patient may swallow it quite unconscious of the terrible effects it will surely give rise to, sooner or later, and these effects may then be confounded either with the symptoms of the disease from which he is suffering at the time, or as a complication of that disease. And thus, whether the administration of poison has been accidental or felonious, the eventual circumstances of the case may easily be such that suspicion is not aroused as to the real cause of the illness or death.

4. Nevertheless, with reference to the number of deaths, in which poison is the recognized cause, and probability that other deaths of doubtful causation may be so caused, the Government have wisely deemed it of the greatest significance to fully consider the degree of security assured to the public against the indefinite multiplication of such cases. I have attempted to point out the shortcomings of the existing rules regarding the sale of poisons, and the actual degree of insecurity which threatens the public safety.

5. The facts gathered by me indicate that so long as a person of practically any age, from ten years upwards, has a few annas at his disposal, he may purchase a sufficient quantity of any one of the many poisonous drugs in the market to take away the lives of two or more persons. Indeed, anyone really desiring to poison another and having sufficient discrimination to enable him to make a selection from among the many available, or rather purchasable, poisonous drugs, meets with no difficulty in carrying out his horrible design. He may be refused at one shop, but with the tenacity of purpose which characterizes the homicide, he goes from one shop to another, confident that he will ultimately achieve his object; as a druggist or chemist declining to serve him, he can be accommodated at a bania's shop, where poisonous herbs and drugs of various descriptions are openly dispensed and retailed, often by boys and girls of tender age, without the slightest question as to their eligibility for such employment. In the course of my 15 years' experience in India, I have come across a large number of cases in which suicidal or homicidal poisoning has been either perpetrated or attempted, because of the perilous facility with which poisons may be procured in the bazaars.

6. I believe that the legislative interference with the sale of poisons is merely nominal, or if there be a statutory

* Chucklers.

prohibition, it is inoperative in practice. Whether poisons are required for homicide, suicide or for the production of abortion, the facilities for their procurement are alike; for, though it may be a fact that druggists of the better class are extremely particular and exercise the greatest possible caution as regards the sale of poisonous drugs, yet the lower class of drug dealers, and especially the common shop-keepers of bazaars, seldom have such conscientious scruples—all is grist that comes to their mill—and if they can make a small profit out of the sale of a poison, they do so with the same eagerness as they would sell a pound of rice, sugar, or dhall. Recently I went into a certain general-merchant's shop and found confectionary of various kinds locked up in the same almirah as "chlorodyne," Fowler's solution of arsenic, &c.

7. It is absolutely necessary to impose penal restriction upon those engaged in the sale of poisonous drugs as to the manner in which they keep, dispense, and sell these agents, and all dangerous slovenliness or carelessness in any one of these respects, should be subjected to the most deterrent punishment possible.

8. In this connection I would avail myself of the opportunity of stating that certain definite rules, similar to those laid down in the Pharmacy Act in England, should be prescribed for the keeping, dispensing, and selling of poisons. The consequence of the inoperativeness of the legislation on these points is that the public remain without due protection against accidents. My own experience leads me to think that stringent legislation is urgently needed, and it is also a matter of general experience that any disaster occurring as a result of the preparation of prescriptions containing poison, any error such as that of mistaking lethal drugs for harmless compounds would probably at the present time be considered a misadventure, and, as such, passed over unnoticed, instead of the law holding some one responsible for such a grave mistake.

9. A qualified Inspector should be engaged to enforce the law in its full integrity by periodically, and from time to time, as special occasion may require, inspecting all shops borne upon the Register, to see that they faithfully and implicitly carry out the terms of these rules, and in case of any non-fulfilment or breach of them, to have the power of suspending the license until such time as the cause of cancellation has been inquired into and, then if the vendor is at fault, to entirely remove his license.

10. People, even Europeans, appear to have no difficulty in obtaining poisons. I take one drug, chloroform, as an example, as it has fallen to my lot during the past two years, to find four ladies with chloroform in their possession—they used to use it for neuralgic headaches and other affections, and when questioned as to whence they procured it, two of them said they "got it from the chemists." One declined to say whence she procured it, and the fourth got it from a medical man.

11. Again, as regards the ordinary business of the retail druggist in dispensing and vending medicines, we know that frequently entirely unskilled and heedless persons are engaged in this work, and we are only too familiar with the mischief resulting from the incompetence or slovenliness of such persons, a large number

of whom, though wholly unacquainted with the properties of powerful drugs and medicines, are allowed to retail them to the public without any check or control. We know to our regret that *banias* or bazaar shop-keepers expose for sale such poisons as arsenic, strychnine, *rashtaphoor* (a mixture of impure chloride and bichloride of mercury), &c., and that either from carelessness in placing the boxes, packets or bottles containing these medicines too near each other, or from ignorance they supply a poison as an innocent drug, and thus either injure health or destroy life. Instances have occurred in which arsenic, for example, has been given in mistake for bismuth, magnesia, or calomel, and some of these lamentable accidents have been the natural results of incompetence and gross ignorance on the part of those who are allowed to retail drugs to the public, and the danger is increased a hundred-fold by reason of the carelessness displayed in keeping in close proximity to each other on shelves, drawers or trays, innocent medicines and poisons resembling each other.

12. But the greatest dimensions of these particular dangers—dimensions in fact which are almost incredible—are reached in the case of the shops of bazaar *banias* where groceries and drugs and poisons are all sold, and where perhaps even foods and poisons are not kept well-asunder. From shops of this description, arrowroot, rice, sago, or something else in common demand may reach its purchaser with a fatal admixture of arsenic. I have seen calomel and arsenic in different papers in the same tray, and all under the care of an ignorant youth. And beyond the limits of the petty village shop-keeper, the careless custody of poisons leads sometimes to their being sold for other matters, and used, even on a larger scale, accordingly.

13. The unrestrictedness with which at present the retail trade in drugs and poisons is conducted, confers—in a curious way, and to an extent which could scarcely have been foreseen—irresponsibility even for mischievous acts. Apparently, the view that the legislature has taken of the matter has been, that the trade might safely be left unshackled by special regulations, and open without special license to all who choose to undertake its practice; on the erroneous assumption that the common law would suffice to protect the public by punishing any druggist, who through his own incompetence or carelessness, or the employment of an incompetent or careless agent, causes harm to any person. But the view taken by the administrators of the law differs from that intended by the legislature, and the absence of special enactment on the subject seems in most instances to be accepted as a ground for concluding that as the law stands—however extreme they may be in degree, or fatal in result—a druggist's carelessness and malpractices are not criminal offences.

14. In nearly all inquests or trials for manslaughter, proof of negligence merely is not sufficient to convict the wrong-doer unless it amount to gross or culpable negligence, but *what* gross or culpable negligence is, has not as yet been clearly defined by law. We learn from the verdicts of juries that the keeping of poisons and medicines similar in appearance close to each other in the same place

is not gross or culpable negligence. So the selling of strychnine for nitre or opium salts, and the indiscriminate keeping of these substances unlabelled in contiguous drawers or packets, until the time of sale, and then labelling the poisonous as harmless medicines, do not legally constitute culpable negligence. The employment of youths whose experience in drugs is so small that they cannot distinguish white arsenic from calomel, or magnesia merely furnishes, by the destruction of life, illustrations of avoidable accident or misadventure, according to law, but not gross negligence on the part of the employer. Evidently the present state of the law signifies that the right-doing druggist shall be free from interference, but that the wrong-doing druggist shall be almost secure from punishment.

15. To carry out the rules detailed below in their integrity, it is absolutely necessary that there should be prescribed an examination as to the efficiency of all those who intend to make the sale of drugs their profession. As it is a desideratum in the practice of pharmacy, that this skilled commerce, in which the greatest care and a certain minimum amount of technical knowledge is necessary, should only be open to those persons whose qualifications for safely practising it have been tested by proper examination.

16. These rules regarding the sale of poisons should be worked under the sanction and strict supervision of the Registrars and the Police Department.

17. Whilst dealing with the subject of the sale of poisons, it may not be inopportune to make a few remarks upon the sale of quack remedies.

18. I was most alarmingly struck with the amount of patent medicines consumed by my *clientele* when I first came here; but I am proud to be able to say that, by consistently discountenancing their employment, I have succeeded in stopping this baneful habit to such an extent, that I can now positively assert that not one of the patients on my list uses such drugs, except we include "Cockle's Pills," "Chlorodyne," and "Jayne's expectorant." The habit is still very widespread, and I regret to have to write that some medical practitioners (*sic*) are largely responsible for fostering the sales of such remedies, while the credulous public either place themselves in the dilemma of bearing testimony either to the possibility of a miracle being wrought by some special panacea, or are the victims of imposture. The consumers of nostrums, that the vendors declare to be capable of curing practically all the ailments of the *nomenclature of diseases*, frequently find that their faith has been misplaced. A single composition, in the form of pills, or "drops" or "syrup," is lauded as the panacea for a great variety of dissimilar diseases, in all their stages. Many of these drugs are either inert, or of very little power, and the most that can be said of practically the whole of them is, that they are not very injurious. But this is not always so, for some of them are very "patent and potent for evil." I have heard of certain local practitioners actually ordering drugs of this kind, and, as if to complete their disloyalty to the practice of rational and scientific medicine, I have heard of their removing certain patent drugs from their original wrappers, bottles and boxes, and dispensing these drugs as if they were of their

own prescription. It is difficult to conceive a more abandoned state of a medical practitioner's mind and habits than that this discloses, or one in which he could display such absolute disregard of the dignity of his calling. It is astounding that any physician possessing, the enlightenment and intelligence the public give him credit for, should not discern in this habit a self-condemnation and an unparalleled short-sightedness. Scientific medicine has enemies enough everywhere to contend with without having to defend itself against such folly as this, perpetrated by its own followers. Surely this section of medical practitioners can find a sufficiently long category of drugs in our recent Pharmacopœia,—a book drawn up by the greatest pharmacologists and therapeutists of the day,—without resorting to the use of quack medicines which is a highly immoral practice, even when adopted by the laity, in so far that whilst rigidly enforcing—solely in the interest of the community—the prolonged scientific and costly education of the legitimate practitioner, the public at the same time accords its approval of the illegitimate and ignorant pretender and charlatan by supporting the sale of their wares not simply to the detriment of the medical profession, but to the injury also of the health of the community.

19. By no class, however, is so great an impetus given to the sale of, and faith in, empirical nostrums, as by the lower class of pharmacutists or chemists and druggists, whose confidential and important business connections with the medical faculty are such that in the true interests of the public, irrespective of their own or those of the profession, they ought, when consulted by a too credulous public to decry, rather than to commend, the use of such agents, and on public grounds alone it would be more than well, were there a general consensus and determination on the part of the faculty to discountenance all chemists who trade in nostrums and traffic in illegal or counter-practice; but imitation is a form of flattery—too often do we meet with local practitioners who deem it a venial error in ethics to prescribe, or even recommend to their patients and friends the use of a quack medicine or secret compound, heedless of the fact that their toleration implies sanction of a recourse to unknown, doubtful, and conjectural fashions of medication.

20. By a curious omission in the legislature and penal enactments, the laws, so stringent for the repression and punishment of fraud, in general, and the adulteration of food and drugs, are altogether silent or inoperative, in regard to the pernicious frauds so notoriously carried on by the host of ignorant and extortionate quacks that infest these parts.

21. The newspaper press, so powerful in the correction of many crying abuses, is unfortunately too ready, for the sake of lucre, to aid and abet the enormities of quackery by the publication of advertisements that are often of the most offensive and most objectionable kind. Honorable exceptions to the once general practice in this respect are, happily, becoming more numerous and, doubtless, would be greatly increased, if medical men individually and collectively were to direct the special attention of the editors and reporters of newspapers, and of periodicals in general, to the immoral tendency and

contaminating effect produced upon the youth and purity of all civilised countries by the disgusting quack pamphlets which are advertised and distributed far and wide through the medium of the press. As the Medical Officer of a large residential college, which educates over a hundred boys and young men from 12 to 20 years of age, I have had opportunities of learning the various ways in which the proprietors of remedies for "secret diseases" reach, or get at, their unfortunate and guileless victims, and I know of nothing more immoral or more nauseating than the machinations by which they entrap the unwary.

22. To those who, like medical practitioners, are in a position to see and judge of the extent of the evil, it is lamentable to find members of the other learned professions so prone to give their countenance, and at times direct patronage, to medical empirics, both by the use of and written testimony in favor of nostrums; but, above all, it is grievous to see the immoral and unjust support rendered to quackery by people of the highest intelligence and the most refined culture. Medical practitioners deserving of the name, as conservators of the public health, are bound to bear emphatic testimony against quackery in all its forms, whether it appears with its usual affrontery, or masks itself under the plausible garb of philanthropy, or the ostensible cloak of religion.

23. The terrible disasters that must necessarily arise, by placing the lives of people in the hands of some of the low-class self-styled medical practitioners, who are, in reality, nothing but ignorant impostors, can scarcely be exaggerated, and would be difficult to limit or describe in writing. I have in previous writings stated that of serious cases of illness, scarcely 1 in 10 are properly diagnosed by certain local practitioners, and this amongst the better classes of patients. What then must be the condition of things among the poorer classes? These practitioners are really quacks in more senses than one, for they go about dosing people with "syrups," and "pain killer," etc., etc., and, in so doing, frequently use their charlatan remedies as if of their own make; this latter fact alone being sufficient to eternally stamp them as dishonest pretenders.

24. The class of men known as Dressers or Hospital Assistants in Government employ—a very useful section of the Medical Department, whose place were they not in existence it would be difficult to adequately fill as they all, locally, get the same medical education as hakims and general practitioners, while some of them are undoubtedly men of high professional attainments, it is natural and legitimate that encouragement be given by promoting the most deserving of them to the rank of hakim, but to permit such men in a half-educated condition to be disseminated broadcast and allowed to run riot as medical practitioners, is a circumstance that cannot be denounced in terms sufficiently emphatic.

25. The remedy for the wholesale charlatanism, now in existence, consists in the promulgation of a peremptory order or injunction, prohibiting all medical practitioners, male or female, midwives and *dhais*, from practising their calling except by a special license, in addition to that license, to do so, obtained from their University College Hospital, or Medical School; this would give the coup de grace to the wholesale imposition to which the public is now subjected.

26. The chief cause of the tardy advance of European medicine in certain parts of India is that it is practised by so many varied grades of practitioners, the professional attainments of the lowest of whom being perhaps at a lower standard than they are amongst practitioners in any other part of the Indian empire. From the classes of men we sometimes see in private practice, it would appear that any person, who has ever been inside a dispensary for a week, considers himself eligible to take up the responsibilities of a private practitioner, to administer to the sick, to relieve the suffering, and take charge of the lives of the ailing part of the community.

27. The man who has served as an apprentice or a compounder on probation in a chemist's shop, or in one of the Government dispensaries for a few months, may be seen, a few weeks, or months, later, driving about in a carriage with his stethoscope and thermometer, pocket case and hypodermic syringe, medicine chest (often filled with the choicest quack panacea), and midwifery bag. From this class of men we pass to the fully developed compounder; and next in order of merit to the student of the Dresser or Hospital-Assistant class, who has failed to pass the first or second year's examination in Anatomy, Physiology, &c., or men of the L.M.S. or Hakim class, similarly circumstanced; or to those students of one or other of these classes who have been reverted to their studies for a year, or actually "failed" altogether in the final examination, or even the dismissed dresser, who is now practising as a physician and is styled by his clients as "Doctor Sahib." We are familiar with many instances of men of these grades who, practising in certain parts of India at the present time, may be seen driving about the whole day and making a few thousand pounds a year, whilst fully qualified, earnest and conscientious practitioners are starving, or are barely able to keep body and soul together.

Indeed we know of men holding excellent appointments, and practising as physicians, who have never had a single day's medical education.

28. The second great cause of the retardation of European medicine in some parts of India is the patronage accorded to the Unani and the Vedic systems; which in curative efficacy, or in knowledge of the nature of disease, is absolutely devoid of even the most remote comparison with modern medical practice. I have, however, sufficiently animadverted on this subject in a previous article.

BURMESE "KWE-NA."

By ASST. SURGN. ARTHUR H. NOLAN, I.M.S.

Civil Surgeon, Moulmya.

BEFORE giving an account of my observations and conclusions on the skin disease known as "Kwe-na" among Upper Burmans, which I believe I have correctly diagnosed as Yaws, I shall record notes of a case I had under treatment at Gangaw in the Pakokku District, shortly after my arrival in Burma in 1889. I had never before heard or read of Burmese "Kwe-na," nor had I during my service in India seen or heard of Yaws there, and the possibility of Yaws existing in Burma did not at the time occur to me. I considered this case either an exceptional manifestation of one of the syphilitic, or a form of "Oriental sore," as the eruption appeared to correspond in

cases respects to the description and representations of Bickers and Grote "Boutons" by Dr. VANDYKE CARTER.

The peculiarities of the case however led me to record the following notes in my diary :—

Gangaw, 17th October 1889.

"A Burman, aged 40 years, from Kale, has on the forehead a cone-shaped fungoid growth covered with a dirty yellowish moist scab. At some little distance it looks not unlike a rupoid excrescence. Base of growth about 1½ inch in diameter, length from base to apex nearly 1". Little pain on pressure over growth, or on removing a portion of the scab, which gives the excrescence a strawberry appearance.

"Skin immediately surrounding base is slightly darkened but not inflamed nor tender; nor, on the contrary, is there want of tactile sensation.

"There is also an eruption of tubercles varying in size from a pea to a medium strawberry and generally round in shape. These are indiscriminately scattered over face, neck, trunk and extremities, but are more abundant on parts where the skin is moist and thin, as the flexor aspect of thighs and arms, neck, pudenda and lips. Some of these tubercles or *boutons* are hard and entirely painless, but most of them are moist from a scanty purulent exudation and scabbed. The moist ones only feel a little tender and the skin surrounding them is slightly reddened. Scabs generally are of a dirty grey or yellow color, some are light brown from oozing of blood. They appear to possess the same anatomical characters as the large growth.

"The man is strong looking and well nourished. No history of syphilis, glands unaffected, no fever, complaints of some pain in joints which are not swollen nor tender. Calls the disease "Quayna," says it is contagious, and he is not allowed by the people to live in his village, nor is he allowed to take up his abode in other villages. No one else in his village is affected with it.

"He contracted it in the Chindwin District, where people occasionally get it. It is not common."

The man was isolated in a small hut, a short distance from my hospital, which he attended daily for over a month. The greater number of the excrescences gradually contracted and fell off, leaving the skin smooth and unimpaired, but marked by spots slightly darker than the surrounding skin.

The large excrescence and a few small ones had not quite disappeared when he left off attending hospital. Treatment was commenced with a purgative and a bath, during which the application of carbolic soap was not spared.

A two-grain dose of quinine was given every morning and ten grains of iodide of potassium with decoction cinchona twice a day. Carbolic oil, 1 in 40, was applied to the eruption.

Later, 2 drachms of liq. hyd. perchlor. were added to each dose of the pot. iodide and the application of dilute citrine ointment substituted for carbolic oil. He was nearly six weeks under treatment.

2. I neither saw a case or heard again of Kwe-na until, in December 1892, I received a communication from Mr. B. C. STREVENSON, Deputy Commissioner of the Yeu District,

regarding the prevalence of the disease in one of the villages of the district named Htanbinzeit.

I quote the following passages from Mr. STREVENSON's letter :—

"Having been aware for some time past that there was a village near Yushay called Htanbinzeit, the residents of which were looked upon as social outcasts by reason of their community being affected with a serious skin disease said to be, by my informants, a kind of leprosy I visited it the day before yesterday morning. ° ° ° The disease is called Kwe-na by the Burmans.

"It is said to be highly contagious, but more especially at one particular time of the year, viz., the month of Wagaung (answering to the latter end of July and first of August) when the sprouts of a kind of bamboo known as 'mhyinwa' begin to shoot.

"Contagion seems to depend on close personal contact, such as eating together out of the same dish, &c. ° ° ° It first commences by the appearance of a sore, which apparently scabs over very soon, but is followed by an eruption which in time covers the whole body.

"The first symptom is great aching of the muscles.

"Persons who suffer from it usually become very attenuated, and this of course is especially the case with those who succumb, ° ° °

"I believe the disease is a very rare one. I have never heard of it before; the Burmans have a great dread of it, and if the villagers of Htanbinzeit were a colony of Thanatophidia, they could not be regarded with greater repugnance by their fellow-creatures.

"I am informed that some years ago, there was a village in the Piginwala portion of the Katha District in which the villagers suffered from the same disease.

"In their case, however, it appears to have been of a more virulent type, attacking the joints and preventing the use of the limbs. ° ° °

3. My temporary transfer from the District soon after receipt of the preceding communication from Mr. STREVENSON, and other duties prevented my visiting, until September 1893, the village of Htanbinzeit mentioned by him, and such other villages where, owing to enquiries previously made, I had heard of Kwe-na.

Notes on some of the cases I examined during that tour, as also a few of the number I have since seen, are given in the appendix to this paper. In parts where the disease is endemic the Burmans and their "Sei-Sayahs" (medicine men) regard it as a form of leprosy.

Following are the results of my observation and enquiries :—

Characters and symptoms of the typical disease.—I am of opinion that in few cases, comparatively, does the disease arise *de novo*, but that it is contracted principally by accidental inoculation, through an ordinary scab, ulcer, or wound, with the virus from a previous case.

The inoculated wound inflames and becomes an unhealthy ulcer, the diameter of which may be ½ to 2 or 3 inches. It is circular or oval in shape and covered with a brownish scab.

It is usually shallow, except in the centre, where it dips. The purulent discharge is scanty and ichorous. The infected sore is called the "Ana-ama-gyee,"

pronounced "Uana-ma-jee," which means chief or primary sore.

After an incubative period of two to eight weeks or more, an eruption, (which may appear on every part of the body except on the scalp which is covered by hair) is observed gradually developing with barely any pain into fungoid growths of various sizes.

When the general eruption appears, the infected sore or "Uana-ma-gyee" usually heals.

The constitutional symptoms vary according to the physique of the individual, state of general health, and the severity or otherwise of the attack.

They are usually, in ordinary cases, loss of appetite, slight depression, pain in limbs, and sometimes fever and anemia.

The tubercles arise from small flat red patches on the skin, often resembling the spots seen on tender skin after flea-bites.

These spots vary in size from a pin's head to a lentil, become papular, are at times itchy, but scarcely painful, even when the papules are broken through into segments, and small yellow points are seen emerging which develop into "kwe-na" tubercles of various sizes.

The eruption may be described as moist, button-like tubercles, resembling granulation tissue capped with dirty grey or yellow scabs formed of the scanty, thin, purulent exudation from them. When a scab is removed another soon forms from the discharge. If blood exudes, as it sometimes does when a tubercle is scratched, picked at, or otherwise injured, the color is imparted to the scab giving it a reddish or dark tinge.

The excrecences are usually round or oval in shape, some well raised, others flattened, and of sizes varying from that of a pea to a size which covers a patch of skin one inch or more in diameter, but the typical eruption in its early stage is about double the size of a well developed small-pox pustule.

At times, after attaining the size of a pea or a little larger, the development of some of the growths ceases, and they dry into hard insensible tubercles and fall off. Others fully develop, then shrivel, contract and fall off, leaving the skin smooth and uninjured. Others, again, spread and flatten, and the scab becomes moister and thinner, exposing the surface of the excrecence, which may break down and ulcerate, or a high crust may form and ulceration go on under it.

In some cases a large single distinct excrecence appears, about one inch or more in diameter at its base, protruding more or less out of the skin and firm. It looks not unlike a roughly cone-shaped lump of putty stuck into the broken skin. Neglect causes it to ulcerate badly.

It will sometimes precede the ordinary general eruption or appear with it; often it is not seen at all.

The eruption is practically painless, unless ulceration occurs.

The margins of skin immediately surrounding the tubercles are (in the ordinary eruption) dark-red or brown, and the tubercles appear set into the skin.

The skin however is not at all sensitive or painful, nor, on the other hand, is there any loss of tactile sensation.

4. *Further*.—The skin affections just described may appear in the disease as multiform.

The Burmese divide them into five forms, each of which I have seen and shall briefly describe:—

1st.—"Kwe-pouk-pouk" (sprouting "Kwe").—This is the typical eruption already described and is the most common.

2nd.—"Kwe-poo-sou"^{*} (elevated ringworm "Kwe").

—The eruption has the same general characters as the preceding, but before breaking through the skin it causes more irritation and some surrounding induration and tenderness.

As it progresses, the tubercles become somewhat irregular in shape, and larger and flatter than the typical eruption. The scab or crust, which is yellow or brown in color, may become thickened, scaly and fissured. When the scab is stripped off an excrecence resembles a large soft bleeding wart, unless ulceration has broken it down.

The central portions of large-sized patches may heal, leaving the skin healthy, with a border of flattened excrecences, thus somewhat representing ring-worm.

This form may appear on any portion of the body, but particularly on soft moist parts, and round the lips and anus. It is clearly as common as the first form and may appear with it.

3rd.—"Kwe-kyet-kyi"[†] (fowls' excrement "Kwe")—from a supposed resemblance to fowls' excrement.—These are very small cone-shaped tubercles, hard and painless. They develop from minute pink patches and have tough grey scabs.

The surrounding skin is unaffected: attacks usually buttocks, extensor aspect of arms, legs and joints, but may appear on any part of the body and with other forms. Is uncommon.

4th.—"Kwe-ta-phun"[‡] (from its supposed resemblance to a broken fig.)—A circumscribed indurated conical swelling at times very painful, is first noticed under the skin which is somewhat inflamed. The skin is eventually broken through, and an ichorous scanty exudation forms a yellow or brown elevated crust over the sore. Removal of the crust exposes a red fungous sore of an irregular circular shape. It may break down and become hollow and cup-shaped with fungoid margins and a tenacious slough in the centre. Appears chiefly on back, thighs and feet.

If it attacks the soles of the feet, the thickness of the epidermis, preventing the growth breaking through for some time, gives rise to a good deal of pain. Not usually multiple. May appear with the other forms.

5th.—"Kwe-bon." (hidden and undeveloped "Kwe").—In this form the Kwe-na eruption does not appear or properly develop. The joints, particularly those of the wrists, ankles, and fingers, become painful and swell. Nodes form, chiefly on the radii, ulnae and tibiae. After some time, if not treated, ulcers (not particularly sensitive) having brown crusts, break out over the joints and shafts of the bones.

* Pronounced Kwey-poo-sou. From "Poo" stagnation and "sou" and irritation or excrecence.

† Pronounced "Kwey-kyet-kyi."

‡ From "Ta-phun-ta" the fig fruit.

The discharges from these spread, cause other ulcerations, and the patient gradually goes down in general health, becoming cachectic and emaciated. If the disease still advances, the ulcers spread and run into each other. Some patches heal while others become deep, filled with slough and are formidable and obstinate. The joints become contracted and ankylosed, the radii, ulnæ and tibiae may become thickened, elongated, and curved^o—from osteo-plastic osteitis probably—nodes break down, and the bones here and there (including at times the nasal and palate) become carious, the hands and feet lose sensibility, and the unfortunate sufferer, after lingering for a few years or more in this condition, dies from exhaustion, if not cut off by some other disease.

6th.—Besides the five preceding varieties I have seen another accompanying the typical form. The Burmese have no special name for it, but call it one of the varieties of "Kwe-na."

The eruption consists of small prominent vesicles clustered together in patches. The patches sometimes coalesce. In a mild case they dry up and heal without ulceration, but in favorable cases they become squamous and fissured and run on to extensive ulceration resulting in contraction of joints, bone disease, &c.

5. *Seat of "Kwe-na" eruption and ulceration.*—As mentioned under "characters and symptoms" and "varieties."

6. *Appearance of skin on termination of eruption.*—Where tubercles contract and disappear without ulceration the texture of the skin usually remains smooth and uninjured. The maculæ are generally dark colored. In cases marked by ulceration the cicatrices present the appearance common to ulcerative processes which have extended to the deep layers of the cutis and connective tissue.

7. *Prognosis of disease.*—Favorable—as far as I can at present judge—if properly treated before the general health becomes badly affected and the ulceration extensive. The disease varies much in severity, from a small crop of tubercles to rhagades and fissures of the skin with extensive foul ulcerations, disease of bone, &c., which render the unfortunate victims helpless cripples until, worn out by pain and discharge, exhaustion brings death.

8. *Duration.*—The usual duration of the ordinary eruption is said to be from six weeks to six months, but it may last for years, with periods of quiescence.

9. *Constitutional Symptoms.*—Pain more or less in limbs, nervous depression and at times feverishness occurs during the commencement of the disease.

If a good crop of the eruption appears, these symptoms abate or pass off. Men and women work, and children play as usual.

When however the disease does not develop in its early stages, or has existed for some time, the patient becomes anæmic, lean, and debilitated, and liable to febrile or other climatic diseases.

10. *Contagiousness.*—It is communicated chiefly by contact and accidental inoculation. An ordinary wound, abrasion, or any affection of the skin where the cutis is broken

or abraded, renders a person liable to the disease, if living in the same house or coming frequently in contact with the infected. The virus of the disease may be conveyed from an affected person to others by mosquitoes, fleas, &c.

People infected in a village are to a certain extent isolated.

11. *Heredity.*—It is not hereditary.

12. One attack does not apparently secure immunity from a second or more.

13. The disease attacks both sexes alike, and people of all ages.

14. *Relation to Syphilis or Leprosy.*—In my opinion none whatever. I have, however, seen two cases in which the manifestations of syphilis appeared to co-exist with "Kwe-na," and believed the individuals to be infected with the virus of each disease.

15. *Treatment.*—In treatment by the "Sei-Sayahs" (native medical practitioners) crude mercury, or the red sulphuret, are the active ingredients in their prescriptions. With the mercury, they generally combine nutmeg, cloves, sesamum, cassia pulp, betel nut,* betel leaf, catechu, pyrothra root and palm-leaf, in powder, as adjuvants and correctives.

In some cases the medicines are administered by mouth, but more often by inhalation. The epidermic method, too, with mercury and fat, is sometimes employed.

The "Sayahs" say that unless the disease is treated with mercury, it gradually progresses with periods of dormancy and death is inevitable.

The process of treatment by mercury—inhalation particularly—is sometimes carried out to the extent of causing most painful and destructive results from extreme salivation.

I have seen cases where necrosis of the palate and nasal bones had occurred from the excessive administration of mercury.

I should think that a few die, while others are left physically wrecked and miserable for life after such disastrously heroic measures.

I can say very little from personal knowledge as regards suitable treatment, having had but few opportunities of seeing the final results of my treatment in a small number of cases of the typical eruption, and in the ringworm variety.

I have used iodide of potassium only in some cases; in others the potassium iodide combined with perchloride of mercury, and latterly, arsenic.

Locally carbolized vaseline, nitrate of mercury ointment and touching the excrescences with sulphate of copper.

In three cases treated with perchloride of mercury and iodide, with the local application of cupri sulph. the tubercles disappeared, but I do not think the disease was cured. In three more cases the same internal treatment caused an increase of tubercles. Arsenic was then tried with benefit.

In one case a few doses only of 5 grains of pot. iodide with ½ grain of hyd. perchlorid. caused severe iodism. Arsenic was then given with benefit.

* It is from this condition the disease derives its name of "Kwe-na." Some, "Kwe," curved bent, and "Na" or "Na" disease, sore.

Disease in which the bones become affected and nodes form, I should treat with iodide of potassium, application of iodine, &c., as for similar conditions in syphilis.

To ulcers, I would apply iodoform or carbolyzed dressings.

Personal cleanliness, suitable diet and good hygienic surroundings would do much towards cure.

In the "Kwe-bon" variety, where joints swell and nodes appear, the native practitioners apply blisters over them, and administer mercury.

16. *General Remarks and Conclusions.*—We have here a disease which, if not yaws (Framboesia) bears a very close resemblance to that peculiar skin affection in its characters, constitutional effects, nature, contagiousness, forms, terminations, and even in treatment by the natives, in so far that mercury is the active ingredient.

I recognise the identity of—

(a) "Kwe-pouk-pouk" with the characters of the ordinary yaw eruption;

(b) "Kwe-pwe-zon" with ringworm yaws;

(c) "Kwe-ta-phon" (and the large cone-shaped excrescence which appears occasionally) with the English "mother yaw" or "Mammian-pian" of French *patois*;

(d) The tough skin covered "Kwe-ta-phon" of the feet, with the "Tubboe" or crab yaw;

(e) "Kwe-bon" and its effects, with those sometimes resulting from undeveloped yaws;

(f) "The vesicular variety," with the form of yaws called "Pian pratelle"; and

(g) The deep ulcerative and destructive phase of the disease with the neglected large intractable ulcers in yaws which cause similar damage and sometimes death.

I would also mention that I consider "Kwe-na" quite as identical in its characters &c., to yaws, as the "Parangi" disease of Ceylon, the "Pian" of Java, "Coko" of Fiji, and the "Verrugas" of Peru, which are now recognised as yaws.

It will, I think, be difficult to trace the origin of "Kwena" in this country. Old Upper Burmans on the Yeu District say it has always existed in parts of Upper Burma. Some Lower Burmans aver they have not seen or heard of the disease in Lower Burma, and Mr. ROBERT C. STEVENSON, who has spent over twenty years in Burma, and has an exceptional knowledge of the country and customs, habits and language of its people, informs me that he had never heard of "Kwe-na" before learning of its existence in the Htanbinzeit village. It may be an endemic indigenous cachexia, consequent on vitiated nutrition from bad hygienic surroundings, exposure and potent malarial influences, and its spread caused by contact and accidental inoculation; or, if its origin by importation be presumed, it must have occurred so long ago that the hope of gaining any definite information on this point from enquiry is very problematical. I see no reference to it in any of the latest works on skin diseases, nor do I remember, ever, seeing it mentioned in medical periodicals. The Burmese are a conservative and reticent people as regards disease and suffering among themselves, particularly if the disease be of a contagious or infectious nature, and I think very few, if any, have sought treatment for "Kwe-na" in any of the dispensaries in districts, where, as far as I at present know, the disease is endemic during the early rains. These are the districts—Yau, Shwabo, Katha, Upper and Lower Chindwin.

DISINFECTANTS; THEIR ACTION AND USES.

ALUM AND POTASH GROUP.

ALUMINIUM CHLORIDE; ALUM'S; AMMONIA ALUM;
BICHROMATE OF POTASH; CHLORALUM; CHROME
ALUM; CUPRALUM; CONDY'S FLUID; IRON
ALUM; PERMANGANATES OF POTASH
AND SODA; POTASH ALUM; THEIR
ACTION, CONSTITUTION
AND USES.

ALUMS.

(482). The alums are the representatives of a numerous class of double salts composed of a sulphate of one of the alkalies combined with the normal sulphate of a sesquioxide and 24 molecules of water of crystallization. Most of these alums are useful for precipitating the impurities in stagnant pools or liquid sewage (with the after addition of milk, or cream, of lime) and thus preventing air pollution. A short description of the principal alums is herewith given.

(483). AMMONIA ALUM $[(NH_4)_2Al_2(SO_4)_4 \cdot 24Aq]$ is obtained (by substituting Ammonium sulphate for potassium chloride when making alum) as octahedra having the same appearance as Potash Alum for which it is sometimes sold (usually being cheaper) as it is capable of equally well performing its, (the potash alum's) duties in the various arts.

(484). When strongly heated all the constituents of ammonia alum, except the alumina (Al_2O_3) disappear and so great is the absorption and disappearance of heat during this evaporation of the ammonia and water that this alum is frequently used for packing the inter-space of the double walls (shells) of fire-proof safes so that should the outer shell become red-hot the inside of the safe will remain below the scorching point of paper.

(485). CHROME ALUM $[K_2Cr_2(SO_4)_4 \cdot 24Aq]$ is readily obtained by the reaction $K_2Cr_2O_7 + H_2SO_4 + 3(SO_3) + Aq = K_2Cr_2(SO_4)_4 + H_2O + Aq$, as dark purple-violet (almost black) octahedra which show a ruby tint; when subjected to transmitted light. If a solution of chrome alum in water be boiled the violet color is rapidly changed to green and crystals refuse to be deposited; but if this green solution be exposed to cold, for several weeks, it will be re-converted into the violet solution from which the alum may be crystallized out.

(486). IRON ALUM, or *Fer-Alum* or *Ferro-Alumen* $[K_2Fe_2(SO_4)_4 \cdot 24Aq]$ occurs as pale amethyst octahedral odorless crystals which are efflorescent on exposure to air and have an acid styptic taste with a slightly acid reaction. It is insoluble in alcohol but is freely soluble in water, even in the proportion of 1:3.

(487). POTASH or COMMON ALUM $[K_2Al_2(SO_4)_4 \cdot 24Aq]$ occurs as semitransparent octahedra which are

usually obtained by crystallizing out the Copperas and then adding potassium chloride to the (remaining) solution obtained by the aqueous lixiviation of roasted alum shale. It is extensively used in the arts as a mordant for calico-printing and for making paper, colors, dyes &c., while its astringent and styptic properties render it valuable in medicine and the ease with which the decomposing alumina entangles matters renders it useful in water purifying.

(468). **CHLORALUM** as it is commonly called is not an alum, but it is an impure solution of aluminium chloride (Al_2Cl_6) which contains some perchloride of iron.

(469). The pure Aluminium Chloride, which is useful as an antiseptic is of little disinfecting, value as compared with iron and zinc salts although it possesses the advantage of being a deliquescent inodorous solid which is not poisonous and is capable of decomposing sulphuretted hydrogen, phosphine and ammonium sulphide. It may be condensed as yellowish-white crystalline scales either by passing hydrochloric acid gas and bisulphide of carbon vapor over heated clay or by letting a current of dry chlorine play on a mixture of pure alumina (obtained by calcining ammonia alum) and charcoal, which (mixture) is being strongly heated in an earthen retort. Thus:— $Al_2O_3 + C + Cl_2 = Al_2Cl_6 + 3(CO)$.

POTASSIUM PERMANGANATE.

(490). *Chameleon-Salt*, (K_2OMnO_4 or $KMnO_4$) is obtained as prismatic crystals that reflect a dark green color but are red by transmitted light. It is very soluble in water to which it imparts a purplish red hue which, according to the degree of dilution, converges to delicate tints of pink: provided the water be pure; but, if there be present the slightest particle of organic matter, the solution immediately turns brown.

(491). This permanganate, which is a far more stable salt than the *Manganate*, acts as a powerful oxidiser on all substances having an attraction for oxygen, as it readily gives up a portion of its constituent oxygen [$10(FeSO_4) + K_2OMnO_4 + 8(H_2SO_4) + Aq = 5(Fe_2O_3 \cdot 3(SO_4) + K_2SO_4 + 2(MnSO_4) + 8(H_2O) + Aq$] and in the presence of a strong alkali it decomposes albumen making it evolve a rather large amount of its Nitrogen as Ammonia, which latter, in water, is usually spoken of as albuminoid ammonia."

(492). When well exposed to air it freely acts as a deodorant and disinfectant and when it comes in contact with organic matter, (especially that in a decomposing state) it is at once decomposed, but freely parting with a largeish proportion of its oxygen it rapidly oxidises these organic matters which it renders innocuous.

(493). It destroys bacteria with great rapidity and freely absorbs sulphuretted hydrogen and, although not quite so powerful as some other disinfectants, it has the advantage of being odorless—Hence it is well adopted for use in the sick room.

(494). **CONDY'S FLUID** is merely a solution of the permanganates of potash and soda, and is protected by patent.

(495). *Permanganate of Soda*, (Na_2OMnO_4) has the same properties as permanganate of potash, than which it is a good deal less expensive.

POTASSIUM BICHROMATE.

(496). *Dichromate of Potassium or Red Chromate*, [$K_2Cr_2O_7$ or $K_2O \cdot 2(CrO_3)$] which is largely used in the arts

for bleaching oils as also for a dye and the basis of many chrome pigments is usually prepared by roasting native Chrome Iron ($FeO \cdot Cr_2O_3$) in the presence of alkali, and carbonate of potash; after being extracted with water it is treated with nitric acid and recovered by repeated crystallisations as beautiful tabular orange-red crystals which have a very great coloring power and are rather powerful oxidisers, whose disinfecting power is based on the ease with which their constituent potash exchanges a large part of its chromic acid for sulphur and the stronger halogens.

(497). When a mixture of bichromate of potash with sulphuric acid is added to some oils, the coloring matter of the oil is destroyed by becoming oxidised at the expense of the chromic acid (CrO_3) contained in the dichromate, and potassium sulphate and a sulphate of sesquioxide of chromium is formed, while the liberated oxygen combines with the oil [$K_2Cr_2O_7 + (H_2SO_4) = K_2SO_4 + Cr_2O_3 \cdot 3(SO_4) + 4(H_2O) + O_2$]; similar reactions take place on contact with other organic substances: whence the valuable disinfecting power of the bichromates is more than double that claimed for carbolic acid

—:O:—

CLINICAL FEATURES OF BERI-BERI.*

By SURGEON-MAJOR D. BANU, I. M. S.

Manbhung.

THE subject of this paper is a disease about which our knowledge is by no means very clear. It is the want of a clear and accurate knowledge of this disease that has prompted me to take up this subject.

From CHEEVERS' Conmentary, I learn that Dr. MALCOLMSON referred to a peculiar form of paralysis of the lower limbs due to peripheral neuritis, and to alteration in the lower part of the spinal cord. In most of his cases there was more or less paralysis; 57 out of 65 had numbness of feet and hand, 40 had pain and soreness, 40 oedema, 33 spasms, 11 had the gait of the sheep, 12 tottering in walking, and 2 a sense of weight in the limbs or thorax (*J. M. G.*, January 1882.)

MOREHEAD says that it (beri-beri) is a general droop of a complicated character. That the blood is sufficient in quantity, but there is water in undue proportion. It is present in the scorbutic diathesis.

As to the cause, he says: "So watery blood and feeble heart predispose and exposure to cold and damp becomes the exciting cause."

The disease he calls beri-beri presents the following symptoms, which may come on suddenly or gradually: weakness, unwillingness for exertion, apression and weight at the epigastrium, dyspnoea, palpitation, quick, small pulse, intermittent and fluttering, scanty high-colored urine, vomiting, anasarca and bloated appearance; serous effusion into the areolar tissue of skin, and into the pleura, pericardium, and peritoneum, pain, numbness, stiffness, with oedema of lower extremities, which subsequently become paralyzed. Among morbid appearances he mentions anasarca, oedema of lungs, hydrothorax, hydropericardium, ascites, cranial effusion. In some cases traces of old or recent inflammation of viscera.

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

Professor McLEAN defines beri-beri as an extremely fatal disease, characterised by anæmia in an extreme degree, ascending motor paralysis, chiefly of the lower extremities, scanty high-colored urine, general œdema with effusion into serous cavities, chiefly the pleura and the pericardium; occasionally acute pain and oppression at the epigastrium. Death occurs generally suddenly either from dropsical effusion into the thoracic cavities, failing at the heart, or embolism. As to causes, he lays stress on climatic conditions unfavorable to health, all of which bring about anæmia or scurvy. As to its relations to scurvy, he says: "I am strongly of opinion that scurvy plays a much more important part as a predisposing cause than is generally accepted." He divides the cases into acute and chronic. In some of the acute cases he says the whole duration of the case does not exceed 24 hours, while there is intense anæmia, paralysis, generally œdema and effusion of fluid into the cavities. He distinguishes the two types of the disease, and says sometimes the paralytic symptoms are marked, in others dyspnoea and dropsical symptoms are more urgent. In all there is evidence of intense anæmia, anasarca, prostration, quick small pulse with subnormal temperature and scanty urine. As to morbid anatomy, he refers to the watery condition of the blood with diminution in the number of red-blood globules and presence of water in every organ or tissue of the body; the heart is enlarged, soft and flabby; the spinal cord is almost always congested, and fluid is found in the spinal cavity.

Sir W. MOORE considers beri-beri to be a peculiar form of scurvy. The symptoms of the disease, according to him, are great debility, stiffness of legs and thighs, succeeded by numbness and swelling of those parts, with great difficulty in using the limbs. Then the body becomes swollen, the breathing quick, and the pulse feeble, while the urine is scanty and thirst great. Diarrhoea and incontinence terminate the illness.

Sir J. FAYRER defines the disease as follows:—

"A disease characterized by anæmia, anasarca, degeneration of muscular tissue, effusion into the serous cavities, debility, numbness, pain, and paralysis of the extremities, specially the lower, pericardial anxiety, pain, and dyspnoea, scanty, high colored urine; and in some cases drowsiness and sleepiness." Among causes, he mentions certain conditions of soil, air, and water, food deficient in quantity, quality or variety. Death results rapidly in some acute cases, with symptoms of effusion into thoracic and abdominal cavities, or within the skull; by exhaustion syncope, or formation of coagula either in systemic or pulmonary circulation. Sir JONESTON suggests that the symptoms might be due to the presence of some kind of hæmatozoön in the blood.

I now beg to place before you, gentlemen, the views held by different observers on some epidemic outbreaks of disease which have been called the "beri-beri," "acute epidemic dropsy," "beri-beri fever," and "acute anæmic dropsy." The first of these outbreaks took place in the criminal prison at Singapore in the year 1875, and continued till 1880. Dr. J. ROWELL, Principal Medical Officer, Straits Settlements, noticed that the symptoms set in either gradually or suddenly, and that they were weakness, lassitude, inaptitude for exertion, general

anasarca, sense of fullness at the pit of the stomach, tension and weight at the pericardium, dyspnoea, vomiting, uneasy sleep, feeble, frequent pulse, fluttering of the heart, muscular spasms, stiffness of the legs and thighs, followed by numbness, later on by œdema, and sometimes paraplegia; with a scarlet aspect the extremities were cold. The bowels were torpid and urine scanty, high-colored, albuminous. The intellect remained unclouded, the gums were spongy. Burning of hands and feet was not observed as a symptom, nor any fever. Mortality ranged between sixteen and twenty per cent. Death sometimes took place suddenly within a few hours.

Soon after this outbreak in Singapore, an epidemic disease invaded Calcutta and its neighbourhood in 1877. It was at first styled the "new disease," and then different observers applied different epithets to it. Some called it "beri-beri" others "acute œdema," others again "epidemic dropsy," and a few took it to be an exanthematous fever. A similar disease also appeared soon in Dacca, Shillong, and Sylhet. Most of the popular practitioners at Calcutta, Native and European, witnessed the epidemic and had to treat cases of the disease. The members of the Calcutta Medical Society took a great interest in the disease, and interesting descriptions took place at their meetings as to the nature of this new disease. There was a great difference in the opinion of different observers.

Dr. SMITH said that scorbutic dyscrasia, which is so prominent a feature in beri-beri, was markedly absent in this disease. Even latent scurvy seemed to be absent in many cases. Nervous pain and sensation of burning were commonly experienced, and discoloration of the skin was noticed.

Dr. HARVEY considered the disease to be beri-beri. He found distinct anæmia in all, and anæmic bruit in several. Anæmia was a constant condition which he found. Many suffered from fever. There was enlarged spleen in many but not in all cases. A few had scorbutic or at least spongy gums. In two cases he found an approach to paralysis of the lower limbs, as if from effusion of serum into the spinal canal, and in a good many more there was great difficulty in walking, apparently not due to paralysis, but to the local condition of the limbs.

Dr. McCONNELL reported that the disease was not at all special or peculiar; that its essence was intermittent fever, with great anæmic exhaustion; œdema of the feet, or in some cases the upper limbs, or even general dropsy occurring in person reduced to low health. Dr. RAMMOY RAO, then in charge of Sambhoo Nath Pandit's Dispensary, Bhowanipur, having returned from Madras, where he had seen 500 cases of beri-beri, had to treat 150 cases of the new disease. He had no difficulty in identifying the disease as beri-beri, which he had treated in Madras.

Dr. COATES had seen beri-beri among the Madras sepoys at Cattaok, and also cases of the new disease, or acute œdema in Calcutta; and he was of opinion that the disease that he saw in Calcutta was not the same as what he had seen among the sepoys in Cattaok, viz., beri-beri.

Dr. O'BRIEN's experience of about 200 cases in Shillong led him to form the opinion that the disease was as contagious as measles, scarlatina, and other infectious exanthemata. He did not find scorbutic diathesis in a

large number of cases. In several cases there was no appreciable fever. He had met with oedema of the lungs, and pneumonia in some cases, and had met with several deaths.

Dr. K. McLEOD, who had ample opportunities to elicit information on the subject of the new disease at the time, has given his views on the subject in the elaborate paper on "Epidemic Dropsy," read by him before the Epidemiological Society of London. He says: "I incline to the belief that the disease was really an exanthematous fever, the dropsy constituting a phenomenon homologous to eruptions of such diseases." Again: "Nor do the nature and course of the disease warrant any suspicion that it was due to any intestinal parasite, similar to that which has been found in Ceylon and Assam, to be associated with the prevalence of anæmia and cachectic states; frequently terminating in dropsical effusion.

Among the symptoms of the disease he mentions: Dropsical swelling of the limbs, occasionally of the body and face. Fever sometimes before, sometimes after, the swelling, in some cases absent; diarrhoea commonly, dysentery in a few; burning and pain in the affected limbs at commencement. Purple livid discoloration of the skin in some cases, disappearing on pressure; urine scanty or excessive without albumen. Dyspnoea, cough and palpitation in most cases, great emaciation, prostration and anæmia. Death often sudden and early. Of the several symptoms dropsy constitutes the most prominent and apparently the essential and indispensable feature of the disease: the other symptoms might or might not be present. Pyrexia, a frequent if not a constant symptom, skin irritation and deep-seated pain in the limbs is a decided feature of the disease. Paralysis was absent. An exanthematous eruption was a feature of the disease in a certain proportion of the Calcutta cases. Disturbances of respiration and circulation were quite prominent phenomena. Anæmia was an essential feature of the disease, but evidences of scorbutic dyscrasia were less marked.

After reviewing the reports on the outbreaks of "beri-beri fever" in different parts of the country, Dr. N. CHEVERSE formed the opinion that the disease belonged to the class of exanthemata, and that the dropsy and the paralytic symptoms were only the sequelæ of the disease. And further he says: "Although its manifestations are numerous and complex, I think that on carefully studying its phenomena we cannot fail to arrive at the conclusion that the acute epidemic beri-beri is not, as some have thought, a group of diseases, but a malady quite distinct from all others, a fever of varying type, but characterized by a very marked individuality." Regarding its relation to scurvy, he says: I think that, when we state the fact that, wherever beri-beri prevails, it specially selects the scurvyed, we are free from the error of supposing that acute beri-beri is an expression of scorbutic cachexia; and regarding its connection with malaria, he says: I think we are justified in concluding that beri-beri is not a malarial fever, but that the victims of malarial cachexia are specially liable to suffer from its effects." Viewing beri-beri in its paralytic aspect, Dr. CHEVERSE says: "One of the leading sequelæ of beri-beri being

anasarcous and dropsical effusion into the areolar tissues and serous cavities, the occurrence of spinal paralysis in various degrees as one of its complications is clearly accounted for." Then he says: "The stiffness of the lower limbs is frequently due to the presence of hard oedema, not to spinal paralysis; but in many cases of beri-beri distinct impairment of motor and sensory power in the lower limbs had been observed."

We may observe how very difficult it was to come to a definite opinion as to the nature of the disease, and how very different were the views held by the different observers. Even Drs. HARVEY, COATES, and RANBY ROY, who had seen true cases of beri-beri in Madras and elsewhere, differed in their opinions; whilst Drs. HARVEY and ROY thought the disease to be beri-beri, Dr. COATES did not. Dr. SMITH also was inclined to think that it was not beri-beri. Dr. McCONNELL thought it was essentially intermittent fever neglected, aggravated and complicated. Both Dr. McLEOD and Dr. CHEVERSE held that the disease belonged to the class of exanthemata, and yet their views were different. While one takes it to be true epidemic beri-beri and calls it by the name "beri-beri fever," and lays particular stress on the fever and eruption on the skin, and considers the dropsy and the paralytic symptoms to be sequelæ of the disease, and considers the malarial and scorbutic dyscrasia to be favorable circumstances, and does not say anything about anæmia, the other thinks the disease to be different from beri-beri and calls it "epidemic dropsy," and says that the dropsy constitutes the essential and indispensable feature of the disease, the other symptoms might or might not be present. Next to dropsy, he considers anæmia to be an essential feature of the disease, and further that fever was frequently present, if not constantly. An exanthematous eruption was a feature of the disease in a certain proportion of the cases only, and that the symptoms were not likely to be due to any intestinal parasite.

This brings us to the outbreak of an epidemic disease called by the name of "acute anæmia dropsy," which took place in the Island of Mauritius in 1878-79. From Dr. LOVELL, the Chief Medical Officer's report, we gather that the most prominent symptoms of the disease were anasarca of the lower extremities often extending to the upper extremities and trunk and seldom to the face, and in worst cases complicated with ascites, hydropericardium, hydrothorax. The premonitory symptoms were diarrhoea or vomiting or both, deep-seated pain in the limb, epigastrium, and abdomen, accompanied with slight fever and in most cases by a roseolar rash. Dr. LOVELL said that the anasarca was one of the most striking features of the disease, and anæmia was a constant feature. He distinguishes "acute anæmia dropsy" from beri-beri. The first distinction is the absence of paralytic symptoms; second, the low mortality (2 or 3 per cent.); third, the presence of the preliminary symptoms of diarrhoea or vomiting, which were absent in beri-beri; and fourth, the presence of the rash which is not met with in beri-beri. His conclusion is that the acute anæmia dropsy is a disease sui generis, not due to malaria, nor identical with beri-beri.

Beri-beri prevailed very severely in 1885 and 1886 in Sumatra and Java, and caused a very heavy mortality, which

and the Netherland's Government to depute Professor FRELHARTING to investigate the cause of the disease, and to suggest preventive measures. Here the disease was characterised by the peculiar paralytic symptoms in addition to the anæmia. Post-mortem examination of bodies showed that the symptoms were due to degeneration of nervous tissues, particularly the peripheral nerves. Professor FRELHARTING discovered a peculiar kind of micro-organism in the blood of patients. Dr. MAX GLOGNER, of the Dutch Archipelago, noticed a constant weariness and painfulness of the lower extremities, and abnormal condition of the heart, shortness of breath. He found that not only the coloring matter of the blood, but also the number of red blood cells, was diminished. He admits that in the course of the disease a pernicious influence on the blood is visible, and he compares beri-beri with malarial fever, and points out certain resemblances between them, including the efficacy of quinine in beri-beri.

Beri-beri is endemic in Ceylon. Here it was that Dr. KYNSEY found the *anchylostoma duodenale* in the intestines of the patients suffering from beri-beri. He attributed the anæmia and the dropy to the presence of these worms in the intestines, and did not recognise any other disease as beri-beri apart from anchylostomiasis.

Surgeon-Captain EVANS considers beri-beri to be due to malaria. He had seen the disease as it prevails in Burma. There the prisoners in the Mandalay Jail suffered from the paralytic form of the disease. He had also seen the disease in Assam, where it assumes the progressive pernicious anæmic type, accompanied by dropy. From careful microscopical examination of blood in each case, he comes to the conclusion that both the forms of the disease have a common origin in the blood poisoning produced by malaria. (*I. M. G.*, December 1892).

Dr. THOMAS, Medical Officer, 17th M. I., in his paper on the subject of beri-beri, gives his views regarding it, after having treated a large number of cases. He says: "In a very large number of my cases the proximate cause was due to the presence of *anchylostoma duodenale* in the intestinal canal; the greater the number of these parasites present, the greater the severity of the disease.

Among the symptoms of the disease noticed by him are: weakness and stiffness of the ankles, legs, thighs, numbness followed by burning in the sole of the foot; œdema, puffiness, swelling and lividity of the face; unsteady, tottering gait; great prostration; scorbutic taint in 41 per cent. of the cases; pain in the ensiform cartilage; loss of sensation in the feet and legs; cutaneous anæsthesia; loss of irritability to mechanical and electric stimuli; tenderness of the gastrocnemii muscles; absence of patellar tendon reflex; spasm of the limbs; dyspnoea hurried; irregular and painful respiration; serous effusion into the cavities; general anæmia; pericardial anxiety; irregularity and palpitation of the heart; great nervous depression; peri- and endo-cardial effusion with failure of the heart; scanty high-colored urine.

This is also the view which Surgeon-Major GILES holds as to the nature of beri-beri and kala-azar, diseases which have prevailed so severely in the province of Assam within the last few years. Deputy Surgeon-General

COSTELLO, Principal Medical Officer and Sanitary Commissioner for Assam, in his Annual Report for 1890, makes special mention of these two diseases. He first describes the peculiarly unhealthy and insanitary conditions in which the people live—conditions which are most favorable to the production of malarial fever, and then gives his opinion that he could in no instance distinguish any cases as being in the least different from a very aggravated form of malarial fever, with its usual results when so aggravated and neglected. Further on he says that "the opinion of the best Civil Surgeons of the province, as well as my predecessor, an officer of great experience, was, and is, that the apparently peculiar form of fever is nothing more than a very aggravated and often neglected malarial fever, and that its so-called distinguishing features, such as anæmia, enlargement of the spleen and liver, with dropy, diarrhoea, &c., &c., are ordinary results of unusually severe and neglected malarial fever." He also recommended to Government that an officer should be specially deputed to investigate into the causes of the heavy mortality from these two diseases.

Thereupon, Surgeon-Major GILES was specially deputed to Assam. Dr. GILES submitted his report in 1890, I believe, but I regret I have not got a copy of his report, and I shall therefore refer to the *resumé* of the report as it appeared in the *Indian Medical Gazette* (June-July 1892). Surgeon-Major GILES did not find any such disease as the epidemic peripheral neuritis of MALCOLMSON in Assam, and after comparing the cases, he came to the conclusion that kala-azar and beri-beri were identical and not two different diseases. Then he says: "The disease is characterized by extreme anæmia, a peculiar leaden-tone of the complexion, while the conjunctiva presents a peculiar bluish-white tint, dyspepsia, occasional attacks of pyrexia, diarrhoea, distressing breathlessness, and finally dropsies of the serous cavities and of the lungs, and cellular tissue. The patient is reduced to a helpless condition. Profound depression of the system, persistently subnormal temperature. The immediate cause of death is commonly either dysentery, pneumonia or bronchitis. The stools of patients contain many *anchylostomata*; and post-mortem examinations of bodies shewed that the intestines harboured these nematode worms in numbers, where they acted as so many blood-suckers." From all these, Surgeon-Major GILES came to the conclusion that the anæmic and other symptoms of the disease were attributable to the presence of this worm in the intestines, and gave the name of, "*anchylostomiasis*" to the disease known as beri-beri and kala-azar in Assam.

Dr. DONSON, late Civil Surgeon of Dhubri, who enjoyed very favorable opportunities of studying the diseases, and who made very careful and searching enquiries into the prevalence of anchylostomiasis in India, is worth referring to in connection with these diseases. Dr. Donson's experiments on the emigrants passing through Dhubri to Assam prove the almost universal existence of the *anchylostoma* in Bengal, Madras and Nepal, when 65-88 per cent. of the healthiest looking of the imported population of Assam is found to be affected with the parasite while in transit from the recruiting districts to the labor districts. In one place Dr. Donson says: "In my enquiries I have noticed numbers of cases where the parasite was

Spinal, but without anaemia was wanting altogether, or not present at first. Again, all the healthy cadavers and prisoners, who, showed not a trace of anaemia, although in a large proportion in them the anchylostoma existed in numbers. In others it had health, the anaemia has been intense and the parasite found; and in several dropsy and anaemia were found but no parasites. These anaemia cases from the first were looked on as cases of beri-beri." In another place Dr. Dobson says: "I contend that malaria has a great deal more to say to this excessive mortality in this district (Goalpara) under the heading kala-azar than Surgeon-Major GILES gives it credit for; and further we have still to learn more regarding the pernicious effects produced by anchylostomiasis before we can credit them with the disease known as kala-azar, and which latter, I take it, is malarial poisoning."

Dr. DOBSON makes a distinction between the kala-azar and the beri-beri cases. In the former cases emaciation is a leading symptom, but anaemia is not generally present. The spleen is much enlarged. Generally there is no dropsy, and there is a history of fever. The beri-beri cases have intense anaemia, at times coupled with dropsy, which may be general or partial, but no enlargement of spleen.

Dr. SANDWICH of Cairo has written an excellent paper on anchylostomiasis. He says the digestive system is first affected and the symptoms begin with pain in the epigastrium, the appetite is affected, sometimes there is an earth-hunger, constipation is a constant symptom, the urine is pale in color and of low specific gravity, with a trace of albumen in most advanced cases, pain in the head, giddiness, pain and weakness in the knees; there is palpitation, hypertrophy of the heart in some advanced cases, dyspnoea and noises in the ears, marked anaemia, pallor, oedema of the legs, diminution in the number of red-blood cells and the amount of haemoglobin, sub-normal temperature and debility and wasting. Dr. SANDWICH is of opinion that the disease is due to the presence of anchylostoma in the intestines. He does not consider his cases as beri-beri, which he says would seem to be a specific peripheral neuritis.

From the above brief survey of the views held by the different authorities in regard to beri-beri, we gather that the term has been applied to different or at least dissimilar diseased conditions of the body, that by one set of observers the disease is considered to be an outcome of scurvy or a peculiar manifestation of that pretty well recognised disease. Among them we find the names of MOREHEAD, MACLEAN, and Sir W. MOORE.

Then we find at least two if not three observers who take beri-beri to be a peculiar exanthematous disease-infectious and having its period of incubation and development and abatement, and its sequelae. One of them, Dr. CHURCH, takes the disease to be a form of fever and calls it beri-beri fever. The other (Dr. McLEOD) takes it to be essentially a kind of dropsy. Dr. O'BRIEN also thought the disease to be exanthematous in nature.

Dr. ROWATT of Singapore calls the disease that broke out there to be beri-beri. Dr. LOVELL of Mauritius takes his cases to be a peculiar form of dropsy due to anaemia.

Then again, we find some who consider beri-beri to be a peculiar manifestation of malarial cachexia, or at least analogous to malaria, and due to similar causes or originating under similar circumstances. Among them we

find the names of Dr. MAX GLOESSEN and Dr. HUGH. We may also mention the name of Dr. CORRAO holding the same view, though it is not beri-beri exactly he refers to, but kala-azar, which he takes to be the result of malaria. Dr. DOBSON also thinks kala-azar to be mainly, if not solely, due to malaria; and even beri-beri is probably not due to what is called by another set of observers to be anchylostomiasis. Among them we find the names of Dr. KYNSEY, Dr. THOMAS and Dr. GILES, and lastly, while Dr. GILES is of opinion that the kala-azar and the beri-beri of Assam are the one and the same disease and due to the presence of anchylostoma duodenale in the intestines, Dr. SANDWICH of Cairo, while admitting that the pernicious anaemia of the tropics is due to the nematode worm, does not think it to be identical with beri-beri but takes beri-beri to be a kind of epidemic multiple or peripheral neuritis as described by Dr. MALCOLMSON fifty years ago, and as has been lately observed by PRONKLEERING and WINKLER in Sumatra and Java. Again Dr. DOBSON, while admitting that a peculiar form of anaemia (now malarial) might be due to the presence of nematode worm, opposes Dr. GILES' theory that the kala-azar and beri-beri of Assam are due merely to the presence of the worm in the intestines, as he has found the healthiest men of different parts of the country to harbour such worms without in the least suffering any evil effects from the same.

THE USES OF NARCOTICS AND STIMULANTS AND THEIR EFFECTS ON THE HUMAN CONSTITUTION.

By RAI KANNAI LAL DEY, BARADUR, G.M.O.B., F.C.S.,

Late Chemical Examiner to the Government of Bengal.

I WILL first review the known varieties of the most important drugs used as intoxicating agents, giving, where practicable, their chemical composition and describing the properties of their constituents. The beverages, or stimulants, properly so called, will come last for consideration. In treating of them, I will devote some space to the description of some of the commonest forms of adulteration of wines, as many serious evils to the system may be traced to these adulterations as much as to abuse of excess and intemperance.

From the use of narcotics and stimulants, in some form or other, by mankind in general, it would appear that the craving for such excitement arises from a natural want, and that the same instinct which drives man as well as the inferior animals to seek for those healthy aliments which contribute to their bodily support and nourishment impels him to seek for these indulgences: whence it may be presumed that their use is a necessity.

First, in the order of these drugs is *Tobacco*, which is generally consumed, in that state almost in which it is found in nature. The changes it undergoes being inconsiderable and, in most cases, inexpensive before it is made fit for human consumption. It is used for chewing, smoking, and snuffing only. In Europe its use is chiefly restricted to smoking and snuffing. In Asia and America all three modes are resorted to, only there is a difference, in manner, according to the tastes and habits of the different people. In Europe the smoke is inhaled either from pipes or leaves rolled into spirals; in Asia the drug is kneaded into a sweet and odorous

compensated and its smoke inhaled through a pipe peculiar to the people who use it. In Europe the weed is preferably consumed in its raw state; in Asia it is softened and weakened. There are races, however, in the East, who, like the Europeans, are fond of smoking the unmanufactured leaves—the Oorias, for example, and some people on the West Coast of the Indian Peninsula, as well as some of the islanders of the Eastern Archipelago. In America smoking is not unfrequent, but chewing is nearly as much a favorite method as is smoking in Asia and Europe. There it is used in the form of quids, which cause a profuse secretion of saliva in the mouth, and it is not uncommon to see ladies and gentlemen in the midst of social gatherings squirt out the tobacco liquid, in volumes, to the infinite disgust of people who are unaccustomed to such sights.

In India also tobacco is used for chewing, which is solely confined to the very lowest classes. Low caste men and women and drain-coolies of the hill tribes, are rather fond of this use of raw tobacco, but I have seldom known them to chew unmixed tobacco. What they do is to take a chip only at a time and chew it with betel and nut. Cigar smoking is least in fashion, and does not seem to suit the Hindoo taste, though it may find favor amongst one or two comparatively barbarous races.

Though very largely used in India, and most other Asiatic countries, snuffing is not so general as is the smoking of manufactured tobacco, to gratify the narcotic appetite. In this latter form it fully satisfies the natural demand, as well as contributes to a luxurious indulgence, peculiar to the national character. With the rich and the well-to-do classes tobacco-smoking is a luxury; but with the operative and the middle classes it is so indispensable a necessity, that a poor laboring man may dispense with some of the necessities of life, for a whole day, but he cannot undergo the deprivation of tobacco for even one hour. Amongst the richer classes generally, it is indulged in not so much for the gratification of an appetite as for luxury and external display. The tobacco of the rich is so much spiced and perfumed that the presence of its chief constituents is scarcely perceptible; amongst them the external array of tobacco-smoking receives greater attention than the practice itself. In large assemblies, and on festal occasions the glittering smoking-apparatus forms an important and conspicuous ornament of a native gentleman's saloon and drawing-room.

The practice obtains amongst the masses of the people, as one of those things which the humblest amongst the people cannot do without; a man may not have the means to provide himself with a decent water pot; his resources may not allow him to replace his cracked and broken stone-platter with a sound one to eat his rice from, but his hooks and its adjuncts will always be found complete. It may be, a family is living on half rations for days together, but they always have the means for entertaining a host of visitors with *chillum* after *chillum* of tobacco, for hours together. A Bengalee's passion for tobacco is a prominent feature in his national

character. And employers make a great mistake if they think they will get a great deal of work out of a laboring man by stopping his smoke, without which he is worse than useless. It is true that much of a laboring man's time is used up in tobacco smoking, but if he be kept without his smoke that time will be wasted in yawning and yawning, or frittered away in trifling with his tools.

People living in the interior, and far removed from the metropolis, for example, are more addicted to smoking and contract it earlier than those living in the metropolis itself. In villages boys in their teens are hard smokers, and the men, also, are most passionately fond of smoking. With the ordinary villager in Bengal nothing short of 50 smokes will suffice during his waking hours while with us eight to ten are ample. And it is to our credit that while smoking is almost universal in this country, it is wholly restricted to the male population amongst the Hindoos. Up-country the pipe may now and then be seen in the hands of respectable Mahomedan females, but it is a forbidden indulgence amongst Hindoo ladies. We should not in this estimate take into account the practices of women who have already set all laws human and divine at defiance in graver matters.

It has been supposed that, next to salt, tobacco is the article most extensively used by man. In Europe, though the duty on tobacco is very heavy, its use on that account is not diminished to any great extent, and the consumption per head varies from 2 to 12 lbs. Besides what is obtained by indigenous cultivation, in India, more than 140,000,000 lbs. are annually imported from America, and the share of distribution for each country of import ranges from 300,000 to 38,900,000 lbs. The largest tobacco consumers, in proportion to the population, are the Germans, and the most abstemious are the Portuguese.

It has been estimated that nearly eight hundred millions of the human race consume tobacco, and the average consumption per head is 70 oz. The total growth is nearly two millions of tons, which at 800 lbs. to an acre would require more than 5½ millions of acres of rich land. One other fact in connection with the effect of tobacco cultivation on the soil in which it is grown. Agricultural chemistry has, by indisputable scientific facts, demonstrated that no crop, that is grown for human subsistence or luxury has so deteriorating an influence on the productive powers of a soil as has tobacco. Vegetable substances, when burned in the open air, leave a residue of inconsumable mineral matter, or ash, the quantity of which determines their exhaustive effect on the soil. The leaves of plants abound in this incombustible ash, and those of tobacco yield proportionally the largest quantity. A dried tobacco leaf, when burned, yields from 19 to 28 per cent. of ash, or the proportion of ash to other matter is nearly one-fourth; and this ash belongs to the class of soil constituents which are most necessary to vegetation. The weight of these constituents withdrawn from the soil is in direct proportion to the weight of the leaves gathered and, bearing in mind the proportion of these ashes to other ingredients, the exhaustion to the soil caused by the cultivation of tobacco may be imagined.

It was a subject of enquiry whether tobacco, in whatever form taken, has any injurious effect on the health of

* The lower classes of the nation perhaps, but ladies never.—Ed., I.M.R.

man. These who appreciate its use on the score of injurious tendency often base their assertions on purely fanciful theories. They have not been able to adduce a single fact based on chemical or physiological research, which would entitle their theories to credit. I cannot, however, forbear mentioning a theory which, though similarly unsupported, is still deserving of consideration as my own experience gives it the color of truth. It has been maintained that amongst the constituents of tobacco, there is some nicotine and empyreumatic oil which have poisonous properties, and which, if inhaled by persons of tender youth, whose organs are in a state of development, have a tendency to stunt their growth and give their bodies an appearance of dryness and emaciation, and that tobacco when indulged in by a youthful pair, will render their offspring diminutive, sickly, and bony;—all these evils, it has been urged, are caused by the above poisons having the power of arresting the inhalation of oxygen in respiration. Whatever truth there may be in the theory itself, the effects supposed are apparent in many cases in this country amongst those who are addicted to an early indulgence of this weed. I will quote some of the other evil effects which tobacco in any one of its forms is said to produce. When smoked to excess, by persons unaccustomed to its use, it produces nausea, vomiting, in some cases purging, universal trembling, staggering, convulsive movements, paralysis, torpor, and death. Another authority says "Tobacco disorders the assimilating functions in general, but particularly as I believe, the assimilation of the saccharine principle. Some poisonous principle, probably of an acid nature, is generated in certain individuals by its abuse, as is evident from their cachectic looks and from the dark and often greenish-yellow tint of their blood. The severe and peculiar dyspeptic symptoms sometimes produced by inveterate snuff-taking are well known; and I have more than once seen such cases terminate fatally with malignant disease of the stomach and liver." Great smokers also are liable to rodent ulcers and cancerous affections of the lips. Excessive use of snuff blunts the sense of smell, alters the tone of voice, and occasionally produces dyspepsia. In rare cases apoplexy and delirium. Drs. PEREIRA and CHRISTISON, however, agree in maintaining that no well ascertained ill effects have been shewn to result from the habitual practice of smoking.

Whence came tobacco to be so extensively and universally used? Is any one of its constituents possessed of the virtues which affect the animal constitution in the same way as most of the edibles are known to do? We know that none of its constituents is capable of producing any of these effects, as will be apparent from the following analysis given by POSSELT and REINMANN:—

| | | | |
|-----------------------------------|-----|-----|---------|
| Nicotina ... | ... | ... | 0.06 |
| Concrete vegetable oil ... | ... | ... | 0.01 |
| Bitter extractive ... | ... | ... | 2.87 |
| Gum with malate of lime ... | ... | ... | 1.74 |
| Chlorophyll ... | ... | ... | 0.267 |
| Albumen and gluten ... | ... | ... | 1.308 |
| Malic acid ... | ... | ... | 0.51 |
| Lignine and a trace of starch ... | ... | ... | 4.969 |
| Salts ... | ... | ... | 0.734 |
| Silica ... | ... | ... | 0.088 |
| Water ... | ... | ... | 88.260 |
| Fresh leaves of tobacco ... | ... | ... | 100.836 |

The only two, of the above constituents, which possess the nutritive principle are albumen and gluten, of which there is less than three parts in nearly 200. But whatever good they do is more than neutralised by a strong odorous poison taken into the constitution in the consumption of tobacco. But even without it, they would not contribute to nourishment, since tobacco is not so used as to come within the influence of the digestive function. There is first the volatile alkali which may be found by infusing tobacco leaves in water, acidulated by sulphuric acid, and distilling the infusion with quicklime, when there comes over, mixed with water, a small quantity of a volatile oily colorless alkaline liquid, which is heavier than water, and to which the name of *nicotina* has been given. It has the odour of tobacco, an acrid burning long continuing tobacco taste, and possesses narcotic and very poisonous qualities. In this latter respect it is scarcely inferior to prussic acid, a single drop being sufficient to kill a dog. Its vapour is so irritating that it is difficult to breathe in a room in which a single drop has been evaporated." The most which has led to its large consumption is the property it possesses of gratifying the appetite for narcotic indulgence in man. But its effects as regards that object can with difficulty be described. Even the heaviest consumer will be at a loss to define his sensations while under the influence of this narcotic. We all know that it possesses no perceptible intoxicating quality. The only thing that can be said of it is that, like many intoxicating drugs and beverages, when once you have begun the indulgence, you cannot do without it. It cannot, however, be denied that it does afford a kind of a relief to the fatigued body after toil and trouble. In habitual smokers, the practice provokes thirst, increases the secretion of saliva, and produces that remarkably soothing and tranquillising effect on the mind which has caused it to be so much admired and adopted by all classes of society and by all nations, civilised and barbarous. We know that it also forms a great aid to reflection. Poets and essayists in our own country, when under the inspiration of the muses, find the pipe to be indispensable to the rapid and uninterrupted flow of their thoughts. To the chess-players the tobacco pipe is an inseparable adjunct. If the supply falls short, they are undone, and find themselves quite incapable of moving the pieces. Tobacco, however, is said to possess medicinal virtue. It is a great antidote to strychnia. A sufficient quantity of the juice of tobacco-leaf administered to the persons affected by the poison has been known to effect a cure. It is also used in some places as a sovereign application to wounds and bruises and the bites of poisonous serpents.

I will now allude to the other drugs. Next to tobacco in the ascending scale are *gunja* and *churus*, both of Asiatic growth, and both are more or less consumed in the East for their intoxicating property alone. There is but one form in which they can be used, which is by burning, in a *chillum* and inhaling the smoke through a tube. *Gunja* is very common in India, and grows in abundance in the Upper Provinces. *Churus* is an extract or resin spontaneously exuded by the plant. In describing how these drugs are obtained, we must speak of the plant and extract together. A plant from which the

resin has been extracted is not fit to be used as *ganja*, to make which it must be dried with the resin, as it is this sticky juice which helps the flower of the plants on each twig to stick with the leaves on it and form itself into a pod. In India art is resorted to to quicken the formation of these pods, and particular care is taken to prevent the plant growing exuberantly leafy. Some say that to quicken the formation of the *ganja*-pods they pour milk at the root of the plant and mix sugar with the earth when it has begun to flower.

The *churus* or juicy extract of hemp is collected from the hemp plant either by scraping with the hand as in Nepal, or by men, covered with leather aprons, running backwards and forwards through the hemp fields and beating the plants violently. The resin thus detaches itself from the leaves, stems, and flowers, and adheres to the leather, from which it is scraped off and formed into balls, known as the *churus* of Cabul. In Persia the resin is detached by pressing the plant on coarse cloths, and afterward scraping it off and melting it in a little warm water. The ordinary *churus* sold in the bazars is the *churus* of Cabul as gathered in Central India. The most valuable drug is that grown in Nepal, and is sold at double the price of the ordinary *churus*. The *churus* of Herat is said to be the most powerful variety of the drug, but it is scarcely known in this country. Another and most economical method of obtaining the resinous extract, is by boiling *ganja* in alcohol, when the extract is obtained pure and is therefore most efficient, while the expense of producing it is small; but this method is not in use in India, and it is not known whether it obtains in any other Asiatic country.

Very little is known of the properties of the chemical constituents of *ganja* and *churus*, except that when distilled with water the dried leaves and flowers yield a volatile oil in small quantity, and the resin dissolves readily in alcohol and ether, and is separated from these liquids in the form of a white powder, when the solutions are mixed with water. The resin has a warm bitterish acid, somewhat balsamic taste, and a fragrant odour when heated.

Both *ganja* and *churus*, are not smoked singly; but are mixed with tobacco before burning them in the *chillum* or *kulka*; with *ganja* the leaf is used, with *churus* the prepared tobacco, which in the latter case is simply mixed in the proportion of nearly 3rds., the whole weighing about a tola. A dose of *ganja* is also nearly of the same weight. A leaf or half a leaf is taken accordingly as a stick or half a stick of *ganja* is used, and both cut into chips on a piece of short thick wood and then pressed in the palms of the hand until the whole is nearly reduced to a powdered ball. The *kulka* used for smoking *ganja* is of a peculiar shape, quite unlike that for tobacco smoking, and the same thing may be said of the *kookah*. Its votaries, before beginning to smoke, always take the same of Mahadeo, with whom it was a favorite drug, and then sit in a ring and pass the *kookah* round, nobody taking more than one or two long-sustained puffs. It is a remarkable fact that in this country the votaries of *ganja* always smoke in company and a stranger falling in with them, though unaccustomed to the drug, is often pressed to join the ring of smokers.

A *ganja*-smoker may be made out by his appearance, which is always dry and rosy—eyes sunken and cheeks flattened. *Ganja* fumes are believed to possess the property of drying up the humours of the body, and giving the persons who inhale them a faded look. A *ganja*-smoker can never be slim, and if the habit of excessive indulgence be long preserved in, it brings on dysentery and diarrhoea. These evils are, to a great measure, counteracted by a wholesome diet of milk and ghee, and native confectionery. None of these effects are perceived in *churus*-smokers.

Much has been said of the peculiar sensations produced while under the influence of *ganja* but I have never been able to elicit what those sensations are even from those long inured to its use. The intoxication produced by *churus*-smoking is much tamer than that of *ganja*, and scarcely brings on any hallucination such as is caused by intoxication generally. Persons under its influence scarcely betray any incoherence in manner or speech, or any perceptible evil in their constitutions. But *ganja* is more powerful in its effects, and leaves a more lasting impression on the system of the *ganja* habitue. One becomes choleric and irascible, rough in manner and rough in speech.

Ganja seeds are sometimes boiled with oil for external application for the cure of cutaneous diseases, while the resins taken in moderation produce increase of appetite and great mental cheerfulness, but excess causes a peculiar kind of delirium and catalepsy. And the prolonged use has a great tendency to affect the nerves, the truth is most strikingly illustrated in cases of intoxication produced by *ganja*-smoking. From the latest reports of lunatic asylums, on insanity induced by indulgence in drugs and liquors, it will be seen that *ganja*-smoking has a more powerful tendency in bringing on lunacy and accounts for more than 55 per cent. of these cases.

Hemp is used in another form in Persia and Arabia where it is taken in the form of *haschisch*, small doses of which produce a moderate exhilaration of spirits, or a tendency to unreasonable laughter. Doses sufficient to induce the *fantasia*, produce an intense feeling of happiness in which the sun shines upon every thought that passes through the brain, and every movement of the body is a source of enjoyment. It is a real happiness which is produced by *haschisch*; by this I mean an enjoyment entirely moral and by no means sensual. For the *haschisch*-eater is happy, not like the gourmand or the famished man satisfying his appetite, or the voluptuary in the gratification of his desires, but like him who hears tidings which fill him with joy, or like the miser counting his treasures; the gambler who is successful at play, or the ambitious man who is intoxicated with success.

When the hemp plant is unusually leafy, the leaves that do not adhere to the flowers on the stems, are gathered, dried, and sold as *sikka*, *subjee*, or *bhag*, which is least in favor in Lower Bengal, but like *ganja* is a universal favorite amongst the up-country people and the Pushtobees, with whom it is more in demand than tobacco is in this country. It is used in two forms, as a liquid and as a paste. In Bengal, in whatever form it is used, it is always uprooted and sweetened.

Madhaka. Indulged in its intoxicating power is very much, but when taken in excess, it quite upsets the man producing sensations by no means agreeable; while under its influence the person feels as if he is resting on his head, and the most familiar objects seem as if they are inverted. Its after-effects are to sharpen the appetite and induce an extraordinary voraciousness. And also constipation.

The name of *sikhs* recalls to the mind even of the most heterodox Bengalee many agreeable associations. It is considered a sacred beverage indispensable on the occasion of those social and family gatherings which take place on the last day of the Dusserah festival, when a cup of the mixture is offered to friends and relatives as a pledge of welcome and friendship.

Sidhas or *bharg* takes the name of *majoun*, which resembles the *hashisch* and *dawames* of the Arabs and Syrians when it is a confection of powdered spices, milk and sugar, mixed with almost an equal portion of *bharg* and formed into cakes, whose effect upon the system of the person under its influence differs very little from that of the other varieties of the drug—*churus* excepted. The sensations produced are of an agreeable and cheerful character, exciting to laughter, dancing and singing, and to the commission of various extravagancies. Hemp in one or other of the forms described is consumed, it is supposed, by at least 300 millions of the human race.

(To be continued.)

A MIRROR OF PRACTICE.

TWO CASES OF PNEUMONIA TREATED BY WET SHEET PACKING OF THE CHEST.

BY ASSISTANT SURGEON PURNA CHANDRA DAS GUPTA, L.M.S. Kishoregunj.

A BRAHMIN lady, aged about 32 years, in her ninth pregnancy and advanced to about the 5th month, was suddenly taken ill with fever and symptoms of influenza which lasted for four days. On the morning of the 5th day she took her usual meal and a cold bath, but in the evening fever came on with renewed vigour and pain in her left side. Her medical attendant suspecting pleurisy sent for me for consultation. I found suspicious signs of pneumonia (Stokes' stage) affecting both the bases posteriorly. Antimony, ipecac, salicylate of soda and other antipyretic and antiphlogistic means were tried, but the disease progressed to the stage of red hepatisation and tended to the whole of the back on both sides, when, on account of the increasing weakness of the patient, the treatment was changed to the stimulating plan. Ammon. carb, squill, senega and digitalis were given internally, a jacket poultice on chest, and brandy, soup and milk were ordered every three hours. But the symptoms instead of gradually abating took a serious turn. The temperature rising to 105°F, the respiration counted 65, and the pulse to 150 beats per minute. I ordered wet pack to chest with water whose temperature was that of the surrounding air, namely 85°F, but as she felt chilly, I warmed the water to about 1° less than the temperature of her body. This acted marvellously; the temperature coming down to 100°, respiration to 55, and the pulse to 120; while the patient fell into a deep and refreshing

slumber. The wet pack was renewed every hour and continued for two days, so as to not allow the temperature to rise above 100°F. Hypodermic injections of quinine, ether and strychnia were used when the patient showed any signs of depression, while nourishment, with small doses of brandy, was continued all along. Resolution commenced on the second day after the wet pack, and she made a good recovery. Her convalescence was however retarded by the occurrence of the miscarriage of a dead foetus on the 15th day from the commencement of her illness. The placenta being found adherent to the uterine walls, it was removed by digital manipulation, and the cavity of the uterus was washed out with Condy's fluid, now and then. From this day her recovery was uninterrupted.

N. P. Bhattacharjee, Hindu, male student, aged 23 years, much debilitated from previous attacks of malaria was laid up with fever and cough, for which some homoeopathic medicines were taken for three days, the fever continuing in spite, a Civil Hospital Assistant was called, who treated him for two days more, but the fever instead of remitting gradually increased to 105°F, and the patient becoming delirious at night I was sent for in consultation and found him very low, delirious, tongue brown and dry, teeth covered with sordid, temperature 102·8°; pulse 120, soft, frequent and weak, respiration 45; bowels loose, passed four or five pea-soup-colored stools during day; answered questions rationally, though the mind was deranged now and then; no abnormal sounds could be detected in the chest, except that respiratory murmurs were weak all over and puerile in the left apex, cough not very troublesome, but the sputa were very tenacious.

This led me to suspect pneumonia, though the symptoms were more like those of a case of enteric fever. There was some gurgling in the right iliac fossa and a distinct rise of temperature of about 1° in the evening. The characteristic rise of temperature by two degrees towards evening was observed for two or three days. Ether, ammonia, bark, digitalis, ammon. and potass. bromide, (for delirium) with brandy and milk every three hours were ordered and continued for two or three days without any abatement of the symptoms. Even when the characteristic rusty-colored sputa made its appearance, and a jacket poultice was ordered, no physical signs of pneumonia were detectable; the pulse and respiration ratio gradually became more and more altered without, however, any very appreciable increase in the temperature, which continued between 102·5° in the morning and 103·5° in the evening, and the patient was gradually sinking. The respiration increasing to 62 and pulse to 150 per minute. I ordered wet pack on the chest, which acted very much the same as it did in the previous case by reducing the fever to 99·2, respiration to 50, and the pulse to 120. This treatment was continued for two days with occasional hypodermic injections of quinine, ether, and strychnia till resolution commenced and the fever left him entirely. Slight delirium, however, remained for a week more and an initial bed-sore being found on the sacrum careful nursing and other suitable measures were taken, under which the patient made a full recovery by the end of the 18th day.

Remarks.—From these brief notes regarding the onset, progress and termination of both these cases, it is evident that the first case was one of acute lobar pneumonia oc-

curring as a complication of an attack of influenza, and the second a case of enteric fever complicated with an intercurrent attack of pneumonia with typhoid symptoms. The absence of any abnormal sounds with the exception of the very weak respiratory murmur and puerile breathing was very peculiar. It was the alteration of the pulse and respiration ratio only that made me suspect pneumonia, which was confirmed by the characteristic rusty sputa appearing at an advanced stage. The chest was examined every day with more than ordinary care, yet no characteristic sounds of pneumonia were detected anywhere. It may be that a very limited and deep seated portion of the inner surfaces of one or both lungs was affected with the disease, and that a very large and superficial healthy surface prevented the sounds being heard distinctly; but the very weak and almost inaudible respiratory murmurs were very characteristic in this case. As the percussion note was clear all over, there was no reason to suspect any pleuritic effusion or any other media to hinder sounds from being conducted externally, nor were the symptoms of that variety called hypostatic pneumonia. Weak breath-sounds, such as are mentioned in works of medicine, are generally found in the beginning of the first stage of acute labor pneumonia and in what is called latent pneumonia occurring in weak and debilitated subjects, but the rusty sputa is generally absent in the latent form of the disease.

It is only in the typhoid variety of the disease that the absence is possible of all physical signs, save the weak breath-sounds that were heard in this case, and the other symptoms, such as sordes in teeth, dry, brown and tremulous tongue and low muttering delirium led me to diagnose this case as that of typhoid pneumonia.

As regards treatment, standard medical works describe three methods, viz., the expectant, the antiphlogistic and the stimulating method. As far as my limited experience goes, the first method is only applicable in those cases where the temperature ranges between 102° and 103°F, the pulse between 100 and 120 and the respiration between 30 and 40. The second method, in my opinion, is not generally applicable to the people of this country, except in a very few robust and strong persons, not even in the very beginning of the attack, for only when given early in selected cases can antimony, so much extolled in inflammation of the lungs, shorten the duration of the disease and mitigate the after-symptoms. The last method is the only one which is generally applicable in all cases of pneumonia in Bengal, but as the affection runs its course like, a specific fever, which it probably is, its course cannot be curtailed by any method of treatment, except the application of cold bath, cold sponging and wet pack, but unfortunately this method of treatment is not as much in vogue here as it ought to be. The tendency of pneumonia, as we know, is to kill firstly by weakening the heart and stopping the pulse, and secondly by the stoppage of respiration. Where there is a tendency towards death by the first method careful and judicious administration of alcohol and other stimulants often saves the patient, but when there is a tendency to stoppage of respiration, stimulants do harm instead of good. I do not find any good or rational plan of treatment of such cases mentioned in any works in medicine. Some advocate bleeding, which is

unsuitable to the people of this country just as is the antiphlogistic method of treatment mentioned above. Dr. FOTHERGILL's recommendation of a hot jacket-position on the chest, which he calls "bleeding a man in his own vessels," is sometimes very efficacious, by unloading the right heart and thus improving the respiratory embarrassment, and it is only here that the so extolled routine plan of encasing a patient's chest in a jacket-poultice finds its best and suitable application, otherwise it is useless or rather harmful in pneumonia, as patients always try to tear them off and become more restless under their use. In my younger days I have lost more than one case from pure failure of respiration, and I now regret that I did not then treat such cases with external application of cold which, as I now understand, would have saved them. Cold bath, sponging or wet-sheet packing, which last is the most convenient way of applying cold (especially in private practice) saves the patient not only in cases of failure of respiration, but as well as in cases of failure of pulse by strengthening the heart, calming the respiratory centres and the whole of the nervous system, increasing the action of the so-called phagocytes, and enabling the blood cells to absorb more oxygen, simply by abstraction of heat. It is true that cold application cannot save a patient when the respiration fails from want of sufficient lung surface to carry on the process (i.e., when both lungs become wholly or nearly wholly consolidated) but such cases are rare, as the failure of respiration is generally due to failure of the respiratory centres by virtue of the heat of the blood and the patient's deficient vitality. A patient with 60 respirations per minute is rarely saved by any other method of treatment than cold application. Limited as my experience is, yet I would recommend this method of treatment in all serious cases of pneumonia, provided stimulants, suitable to the requirements of each case, are also administered.

In conclusion, I would like to be enlightened by any of the readers of the *Record* as to whether a specific fever with a definite course to run can, when occurring as an intercurrent disease to another specific fever, so modify its course as to bring on its crisis earlier than may usually be expected, as exemplified by the second case above described.

PERMANGANATE OF POTASH ANTIDOTES A CASE OF POISON BY A VERY LARGE DOSE OF OPIUM.

By S. M. CHINNIAH, C.M.S.
Medical Officer, Nandura.

HAVING read in the *Indian Medical Record* of the experiments made with permanganate of potash in poisoning by opium or its alkaloids, I send you the following notes of a case I had the opportunity of treating:—

At 6 P.M. of the 22nd July 1895, while about to leave the dispensary to visit my out-patients, Mr. MARWATHI PEEBAJEE, Assistant Permanent Way Inspector G. I. P. Railway, Nandura, came running towards me and begged me to immediately see his only son, aged about 2 years, who had accidentally got hold of the opium box in his house and swallowed the smaller of the two lumps that

the tin box contained. This occurred at about 3 or 4 a.m. while the mother was absent from the house on some business.

Hastening to the railway station where he lived—a distance of about 500 yards from my dispensary—I found the boy fully narcotized and giving him *vin. ipecac 3ii (raw)* directed the parents to remove him to the hospital without any further delay. Sending them off to the dispensary, I took charge of the opium tin, and on enquiry at the opium vendor's shop elicited that on the previous day the father of the boy had purchased from the shop four annas worth of opium, weighing 6 mashes (90 grains *avoirdupois*); now as the opium left in the tin weighed 70 grains, it was clear that the boy had taken a ball of 20 grains, a very large dose I think, and a powerfully lethal one.

On arrival at the dispensary at 7 p.m. I again administered *ipeocacuanha vin. 5ii* and plenty of warm water to encourage emesis, but with very unsatisfactory results; for the boy would not vomit at all. At 9 p.m. this line of treatment appearing worse than hopeless, I dissolved 8 grains of potassium permanganate in one ounce of water and administered a teaspoonful every ten minutes, till midnight, when, the first 8 grains being used up, I had to prepare another quantity of 8 grains, and gave it in the same dose, every twenty minutes. A decided change set in by 2 a.m., when the stupor was replaced by wakefulness and the narcotic symptoms gradually giving way consciousness returned at 4 a.m., when the boy was able to recognise faces and correctly reply to questions put to him, though still unable to stand on his legs. The permanganate was now discontinued, and at 6 a.m. the boy was out of danger, able to stand and speak well. I detained him all that day and sent him home in the evening. In all the boy had only 16 grains of the permanganate of potash to bring him to complete recovery.

The second quantity of the mixture of 8 grains of the permanganate was mixed with (20) twenty minims of *acid sulph dil.*, as recommended by Dr. WILLIAM MOORE of New York, in the *Record*, dated 16th July 1894; but this mixture appeared to have had an irritating effect on the fauces, making the boy cough every time the mixture was given. Spts. ammon. aromat. in 10-drop doses in water removed the unpleasant cough symptoms, and he is quite well now.

Remarks.—Considering the large quantity of opium (20 grs.) swallowed in this case, and the recovery made from the comparatively small amount of the permanganate of potash (*i.e.* 16 grs.) used, I think the case worth noticing. I see from the reports in the *Record* that Dr. MOORE of New York on one occasion used 3 grains of the potash for 2 grs. of *morphia*, and on another occasion 4 grs. of the permanganate for 3 grs. of *morphia*. Dr. BRICARD used 16 grs. of permanganate of potash for 4 grs. of opium; whereas this case required 16 grs. of permanganate of potash for 20 grs. of opium. Thus it will be seen that the administration of the antidote materially differs in individual cases. A standard to go by would, I think, answer better.

By laying down the proportionate quantity of the permanganate of potash required to neutralize the poisonous effects of a proportionate quantity of the poison, *vis.*, opium, *morphia*, &c., I am sure our big heads will draw out a

line, which is so important for India and its children (I mean opium-eating children) who succumb to this dreadful poison year by year owing to the gross neglect or culpable carelessness of their parents in keeping their opium tins, boxes, &c., for, once these vessels get into the hands of a child, who is accustomed, daily, to small doses of opium, it thereby becomes accustomed to its bitter taste, and will surely swallow larger quantities of the drug than is safe.

Surely the profession throughout India ought to be indebted to Dr. WILLIAM MOORE of New York for his valuable discovery of an antidote to a very common but powerful poison.

PUERPERAL PHLEBITIS IN LEFT THIGH TERMINATING IN ABSCESS, COMMENCING 20 DAYS AFTER CONFINEMENT.

By C. A. THOMMAN, C.M.S.

Civil Dispensary, Tellicherry.

The object of reporting this case is to show the lateness of the evidently puerperal lesion.

Mrs. B., Eurasian, aged 24 years, in comfortable circumstances, had sudden high fever (105°F) twenty days after her fifth confinement; her confinements are annual, but natural and attended to by a diplomaed midwife. She is of a sanguine and susceptible temperament, and suffers from intermittent episcleritis* since her fourth confinement, and now (seven months after recovery from the disease under report) she has had a small line of opacity at the outer margin of her right cornea. Her lochia continues for the usual period, and she gets her catamenial flux on the 28th day after confinement, even during the illness under report. The inflammatory symptoms commenced on the 3rd day of the fever by pain and redness on the inner side and upper part of the left thigh, and phlebitis was diagnosed on the 7th day while an abscess which formed above the inner side of knee on the 15th day, was opened as soon as possible and healed in a few days; the pain now extended to the calf, the fever lasted a month with remissions. Soon after the subsidence of the fever she was able to move about under a tonic and supporting plan of treatment, but the induration of the vein persisted for about three months.

Elephantiasis is common in these parts and commences in a similar way but the fever disappears in three days and a general swelling descending on to the foot is the only lesion left.

* A term used by a consultant for a mago-like projection, covered over by congested conjunctiva, in the white of each eye, appearing and disappearing at intervals of a few weeks and for which he prescribed a course of "Syrup Ferri Iodid."

A CASE OF COBRA-BITE TREATED BY FREE EXCISION AND THE APPLICATION OF PURE CARBOLIC ACID: RECOVERY.

By EDWARD BALM, C.M.S.

District Surgeon, Farbani.

MYBOOB KHAN, *et.* 36, was bitten by a full-sized cobra in the calf of his leg when he was at work in the field. He was brought to my hospital within 10 minutes of the occurrence. He complained of a tingling pain

only at the seat of the two bites. The bites were freely excised and bleeding was promoted; the parts were then touched with pure carbolic acid and dressed with carbolic oil. Internally, 10 minims of liquor aminonia were given every hour. The patient was kept under observation for five hours, and he had no unpleasant symptoms whatever.

:O:

BELLADONNA IN SYNOVITIS.

By ASSISTANT SURGEON A. BEALE, I. M. S.

In Medical charge R. I. M. S. "Clina."

I ADMITTED into the ship's hospital on the 15th May 1895 a stoker, suffering from acute synovitis affecting the right knee joint, which came on ideopathically, as special enquiry regarding any injury elicited no response. The duration of disease in its acute stage, and the period passed before resolution commenced, was 28 days; the symptoms were heat, pain and swelling of joint, which increased daily, till it was twice the size of its fellow of the opposite side; the sac was fully distended and appeared as if about to suppurate. The absorption of serous fluid occupied about 15 days, some thickening and tenderness remaining, which disappeared after another fortnight's treatment. Locomotion was strictly interdicted, except for natural purposes only. Glycerine of belladonna, iodine, liniment of belladonna, hot fomentation, unguent hydrargyri, and the elastic bandage, when inflammation had sufficiently subsided to allow of its use, were each applied in turn.

Potassii iodidi, tincture belladonna, and spt. ammon arom. were freely exhibited internally, with an occasional dose of calomel. This case ran through rather a protracted course, about two months elapsing between date of admission and discharge. I was hopeful that the treatment with the belladonna preparations would have acted more speedily and as efficiently as in a previous case, which I had had under my care, in which the symptoms were just as marked, and due to injury, but 10 days saw the disease in this instance run its course. The liniment of belladonna, and nothing more, was found sufficient to accomplish the needful here; it was rubbed gently into the knee thrice daily, with very good effect indeed. I am not discouraged; for perhaps, had I not used belladonna, the case under report would have run a much longer course. I have seen marked, and fairly long standing sacitis in a boy with all its accompanying discomforts, considerably and quickly reduced by means of the glycerine of belladonna applied over abdomen—much to patient's relief and satisfaction.

TRIONAL IN INTERNAL DISEASES.

SPITZER, who watched the trial of this hypnotic at *Drasche's* Clinic, where it was given in doses of from 1 to 2 grammes, (i.e., 15 to 31 grains) draws the following conclusions about trional (1). As useful an hypnotic in heart and lung cases as it is in various forms of psychoses. (2) Quickly induces a normal sleep, which *ipse* reasserts the following night, sometimes however the patient remains stupid with sleep for the whole of the next day. (3) Circulation and respiration not harmed in any way. (4) Retching and vomiting on waking occurred in one or two isolated instances (5) The effects closely resembled those of morphine, to which however it (trional) was superior in insomnia resulting from the pain, &c. of intercostal neuralgia, cancer, rhealgia, sciatica and tabes.

OUR PICTURE GALLERY.

SURGEON MAJOR-GENERAL JOHN PINKERTON

M.D. (GLAS.), L.R.C.S. (EDIN.), F. B. U.,

F. F. P. & S. (GLAS.), I.M.S.

Honorary Physician to the Queen.

THE following biography should point a strong moral to the junior members of the I. M. S., and to all the members alike of the medical services, whether native or European, as this life was a steady and progressive one of hard, practical and administrative work. Briefly, JOHN PINKERTON who was born at Glasgow in March 1833, was a son of J. PINKERTON, Esq., of Hogganfield, and was educated at the Glasgow University: After obtaining the licence of the R.C.S. (Edin.) he graduated in the medical section in 1856 but during his student days he took first-class prizes twice and was a successful competitor for a medical commission at the second examination held by the Honorable East India Company. His first commission is dated August 4th 1855, when he left for India via the Cape of Good Hope, reaching Bombay in March 1856. Facing the authorities on his arrival, he resolved to resign his commission; but was ordered to Aden, where he served first with the 86th Regiment, then with the 18th Bombay Infantry, and acted as Civil Surgeon till towards the end of 1856 when, being lent to the Indian Navy, he accompanied the force under SIR JAMES OUTRAM, sailing up the Persian Gulf in the *Tigra* and was present when *Kharap* was formally given up to Persia. The *Tigra*, which collided with a large ship, during a storm, was sent to Bombay to refit early in 1858, when he volunteered for active service in Central India but was informed that he would first have to complete his two years with the Navy. In 1860 he was appointed Civil Surgeon and Registrar at Broach, where he had charge of the European sailors and some thousands of of native workmen who were engaged in constructing the great iron bridge, over the Nerbudda. On passing the test-examination in Hindustani in 1862, he was appointed Superintendent of Vaccination in Sind, where for the next five years he worked most arduously for (as he states privately) nearly 10 hours a day, almost doubling the number of the vaccinated in this Province—the numbers rising from 42,282 in 1862 to 67,941 in 1869.—and affording a great check to variola, which raged in the district owing to the prevalence of inoculation and its terrible after-results. He passed the test in the Shodhi language and received the reward of Rs. 500 in 1868 when the Bombay Government appointed him Superintendent-General of Vaccination—in return for his work in that direction—and created him a J.P. of the territory while the Syndicate elected him a Fellow of the Bombay University. During the following year the city of Bombay authorities wishing to make vaccination compulsory within the city boundaries, his advice was sought and his aid requested to draft a Bill which, a few years later, was passed by the Legislature under the short title of Act I. of 1877, which provided that every child should be vaccinated within 6 months of birth, and *de facto* this self-same Act was the prototype of the more recent Indian Vaccination Statutes. During this year Dr. BLANK arrived at Bombay with a supply of animal vaccine lymph with which he

Vincent J.
John Puckerton

inoculated a belfer in the presence of DR. PINKERTON and the late Assistant Surgeon ANANTA CHANDROBA; the success attending this experiment gave impetus to the introduction of animal vaccine lymph into Bombay, and beginning from this period cow lymph completely replaced the use of human lymph in the city of Bombay, but vaccination direct from the calf was practised in some large cities, such as Poona and Karachi. Strange as it may appear the Hindus of Karachi objected at first to cow-lymph, whereas those of other cities at once grasped the idea which they hailed as a great improvement, and infinitely preferred it to humanised lymph. During the year 1870 DR. PINKERTON went on Government tour through Upper and Lower Bengal and the Madras Presidency so that he might personally ascertain how vaccination was carried out in various parts of India with the view to draw up a scheme for the re-organization of the Vaccination Department of the Bombay Presidency. This scheme, which has been entitled the Bombay System of Vaccination, was duly laid before the Government, in 1871. This collection of regulations so extended and improved the existent powers controlling vaccination as to give a great impetus to the increased production of this important branch of sanitary reform by greatly increasing the number of public vaccinators. The result was an enormous increase in those annually vaccinated. In 1869 the number of those primarily vaccinated was 464,667, while in 1890 it reached 885,260. Under DR. PINKERTON'S suggestion the Sanitary and Vaccination departments were amalgamated and placed under the supervision of the Sanitary Commissioner. His contemporary, the Editor of the *Times of India* styles him the father of vaccination in Western India. He was promoted to Surgeon-Major in 1872. In 1876 DR. PINKERTON came to Bombay as physician to the European General Hospital, which at that period was located in wooden sheds on the old fort walls; but in 1877 it was removed to another insanitary quarter, the converted Artillery barracks of Fort George. For the next six years he held medical charge of this hospital, where he won golden opinions from all his patients, both needy and rich. It was during this term of office that he performed (1879) the first successful operation of ovariectomy (on a European woman) in India which case he communicated, with some others, to the *Lancet* in the form of "fugitive articles" (his own name for them) in the same year. His "*Remarks on Enteric Fever among my patients in Bombay*," published that same year, contained expressive confirmatory of the fact that typhoid was one of the fevers to be contended with in India, though, at that time, such a suggestion was a novel one still all subsequent literature has served only to reiterate his experience. During his residence in Bombay city, he manifested the greatest interest in the University of which he was already a Fellow. He held the post of Syndic to this institution to which he was also Examiner in Medicine, and twice Dean of the Medical Faculty. He joined the Municipal Corporation and always proved himself a strong supporter of the Scottish Orphanage School at *Mahim*. While he held the post of Hospital Physician, the Government of Bombay erected St. George's Hospital, a magnificent building with all the latest sanitary and medical improvements for the treatment of both European and Eurasian patients, and situated near

the site of the old Artillery Barracks. In 1880 DR. PINKERTON and Surgeon-Major HATCH collected careful notes of fever cases with the results detailed above, and at the request of Surgeon-General BEATHY a summary of nine cases of enteric fever was also written out in a paper that was afterwards published as an appendix to the "Report on the administration of Civil Hospitals in 1880." Taking an active part in corporation and charitable institutions as a member of the Municipal Council for Bombay for some years and part of the time on the District Committee for Karachi, he was (1882) made President of the Medical and Physical Society of Bombay, as well as a member of the Managing Committee of the Bombay branch of the Royal Asiatic Society. That same year he was appointed Deputy Surgeon-General to the Sindh Division, with full control over both Civil and Military duties; and while P. M. O. of that province for five years, many of the hospitals in the district underwent marked improvements in every respect, and a few new dispensaries were opened: thus officially proving his administrative capacities. On the retirement of Sir WILLIAM MOORE, K.C.I.E., in 1883, he was appointed Surgeon-Major-General with the Government of Bombay, which status he held for the full (allotted) term of five years. During this period of his long service, at the instigation and under the active co-operation of Surgeon-General PINKERTON, the Government greatly enlarged the scope of the public medical institutions in this great Presidency in which the undermentioned establishments remain as so many lasting memorials of this able officer's acumen and zeal in sanitary administration in this important part of our Indian possessions *via.*, Bai Mothibai Hospital for lying-in women; the Sir Din Shaw Manockjee Petit Hospital for Women and Children; the Dwarkadas Lallabhai Dispensary; the Amabhai Bhownuggree Home for native nurses; the Allbless Hospital; and the Franjee Petit Laboratory; while among miscellaneous institutions may be mentioned the new European General Hospital at Aden; the Ripon Hospital (Ahmednugger); the Lord Harris Hospital at Nassick; and an increase of some 30 new dispensaries. Scanning the above list one may readily see the grandeur and immensity of the work set in motion by this distinguished officer, who, when there was disaffection among medical officers owing to the usual leave being stopped on account of numerical weakness in the service due to the prevalence of famine and the breaking out of the Afghan War, tried to obviate the difficulty in one of two ways:—(1) By a careful arrangement of relief, so as to give every officer and subordinate the leave he had earned, when possible to grant it; (2) to improve the buildings of civil hospitals and dispensaries as far as possible. He received a distinguished service reward and was the first President of the Bombay branch of the British Medical Association; while in 1893 LORD HARRIS nominated him member of the Bombay Legislative Council—a distinction that has been held by only three members of the I. M. S., and this at long intervals of time, on retiring. From Bombay in 1893 he bore with him the good wishes of many medical officers who assembled to give him a farewell dinner, at which he received the thanks and good wishes of all and in bidding them adieu, made the following remarks which were calculated to endear him to India's suffering poor for all time:—"India has been kind to me. I have enjoyed excellent health, and shall leave this country with many kindly thoughts of this sunny land and its people." On reaching England he was appointed Honorary Physician to H. I. M. Queen Victoria and Fellow of the Faculty of Physicians and Surgeons, Glasgow. In a recent letter he says that he is still in excellent health, despite the almost Arctic winter just passed in Enland. He expresses himself most cheerfully that he is interesting himself strongly in the future welfare of his *alma mater*. May he continue to do so for many long years more is the personal wish of each of his many friends.

THE Indian Medical Record.

1st September, 1895.

SIR WILLIAM ROBERTS M.D., F.R.S., ON THE
GENERAL FEATURES AND THE MEDICAL
EFFECTS OF THE OPIUM HABIT IN INDIA,
AND THE RECKLESSNESS OF THE
EVIDENCE ON WHICH HIS CON-
CLUSIONS ARE BASED.

IV.

Opium-smoking in India.—The smoking of opium in the form of *madak* and *chandu* as compound with the habit of eating opium in India is comparatively modern. The latter habit is coeval with opium cultivation, the former, an exotic, is not traceable to a period anterior to the beginning of the present century. Whatever excuses have been framed to palliate the habit of opium-eating—and as we have seen already they are many and various—no one has come forward to defend or excuse the opium-smoking habit. It is well to keep this in view in considering this habit, as it is the root and origin of the whole antiopium agitation. It was the scenes of domestic misery, personal depravity and debauchery witnessed in the opium-smoking dens of China that first attracted attention; and as the evil spread, and became national in that unhappy country, observers turned their attention to India, where they found the smoking habit taking firm root and spreading rapidly under the fostering care of a civilized Christian Government. The appointment of a Royal Commission followed the investigations of which were limited to India, and to the consideration of the habit of opium-eating both side issues of the greater question of opium-smoking in China and India. In China and the Straits, opium is usually smoked in the concentrated form of *chandu*. The whole of the export traffic in opium, or what is, departmentally known as "provision opium," may be said to be consumed in the opium dens of China and the Far East. In section IV of their Report, the Commissioners tell us that—"The quantity of both Bengal and Malwa opium exported to China and the Far East is thus far larger than that consumed in India, to which it bears the proportion of 12 to 1." The energies therefore of the Royal Commissioners were really concentrated on hearing and taking evidence in regard to a fractional part ($\frac{1}{12}$) of the great opium traffic. That fraction indeed—if we exclude opium-smoking in India—is so minute in itself, that it has never attracted much attention; and because it is not a public but a private and secret habit, it does not propagate itself as opium-smoking does. It is far otherwise with the habit of opium-smoking. It demands for its supply (including India) about fourteen times more opium, and yields fourteen times more revenue to the Indian exchequer than opium-eating does. It is a social and public vice, hence more calculated to attract victims and propagate itself than the nocturnal and less pernicious habit of opium-eating. It will thus be seen that the real question which the Opium Com-

mission should have considered has received very little attention, while the fractional portion— $\frac{1}{12}$ of the whole question—has been evidenced, defended, palliated, and excused by a variety of devices and curiously conflicting theories, till the real issue—opium-smoking—has been lost sight of. It does not require great penetration on the part of the reader to understand how this has come about. It was no accident. When the Commission was appointed, it was intended that thus it should be. We must therefore bring the reader back to first principles on this subject, and remind him that it was chiefly the opium-smoking habit in China, in the Far East, and in India that drew attention to the traffic, and revealed the sensual purposes for which it is so largely used.

The pernicious nature of the habit of smoking opium was early recognised in China and India. In China the habit is traceable to as early as the end of the 17th century, and "by the year 1729 it had grown so common in some parts of China, that it drew down an imperial edict severely prohibiting opium-smoking shops and the sale of opium for smoking purposes." In the year 1769 an edict, which was issued by the Governor of Canton directly prohibited the import of opium. Sir J. B. LYALL one of the Commissioners, in his Memorandum II attached to the Commissioners' Report says of this edict:—"It is a very strong denunciation of the opium habit as morally and physically degrading, and as ruinously expensive." The report informs us also that "in the early Bengal regulations referring to opium, the use of *madak* was forbidden," and in the North-West Provinces and Oudh "the sale of *madak* was prohibited until 1863." Thus we see that the early legislators of China and India—heathen and Christian—saw and endeavoured to arrest the evils due to opium-smoking. One of the two Hindus on the Royal Commission—HORIDAS VEHARIDAN—says of this habit "The practice of opium-smoking is generally condemned; but nothing short of its abolition by law will, in my humble opinion, put an end to it. It is most desirable that it should be made penal." Even Dr. CROMBIE in one of his better moments said:—"I think there is a consensus of opinion among all, including opium-smokers themselves, that the *chandu* and *marlak* manufacture should be abolished." The "Heathen Chinese," the Imperial and Local Governments of China, denounce the habit in the strongest terms they can employ; the early regulators of the opium traffic in Bengal; the Hindu Commissioner of the Royal Commission on opium, the Government of India, and all the local governments, except Madras, acknowledge the unmitigated evils of the habit, and condemn it. But a Royal Commission composed of educated civilized Christian Englishmen—with one honorable exception—takes refuge under the amazing opinion of the medical experts, who unblushingly tell us—after hearing the unanimous testimony of all India, Governments and peoples in condemnation of the habit: "That it cannot be said to be adequately proved that moderate opium-smoking, taken by itself and apart from disease or semi-starvation has any prejudicial effect on health." The Commissioners however admit because they could not deny it, that "On the other hand it was clearly shown before that native public opinion generally condemns the habit as disgraceful."

and this opinion is shared by the great majority of European witnesses official and private—judges, medical practitioners." Yet Sir WILLIAM BURNES, who should have been the first to recognise this universal condemnation of the habit by heathens and Christians, officials and non-officials, medical officials and non-official medical practitioners—plays with words and tickles the fancy of the public with the verdict of "Guilty but not proven." The Blue Book on the Consumption of opium in India, presented to both Houses of Parliament in 1892 gives ample evidence of how local governments in India regarded this deleterious and degrading habit; and on the evidence laid before it from local governments the Government of India concluded as follows:—"Nevertheless we have decided that the policy instituted in the Punjab (total prohibition of smoking shops) is, as the whole, the right one to follow, or at least that it should be given a trial on a large scale." Were any further proofs necessary to convict the medical expert of clinging tenaciously to preconceived theories after their groundlessness had been exposed, their utility denied, and their claim to scientific recognition exploded, we could bring them forward, but that is unnecessary.

It was foreseen from the beginning that local governments would endeavour to evade the orders of the Government of India, prohibiting the consumption of opium on the premises. We are revealing no secret when we state that the orders in question found no favor with the governments of Bombay and Bengal, and that consequently the executive winked at the continuance of the habit under the form of separate dens removed a few feet from the opium-selling shop. In Bengal we affirm that the smoking dens in most places are just as they were, and show no semblance even of complying with the orders of the Government of India. India is the country of evasion, it is the most frequent and most effective weapon employed in our law courts—breaking the law in spirit, but evading it in the letter. It may be imagined then, what potency lay behind the governments of Bombay and Bengal when this popular force, backed by the effective omnipresent machinery of a European and native executive,—was set agoing to neutralise the orders of the Government of India on opium-smoking. These orders in Bengal are a dead-letter, and that for three reasons:—(1) the permission now given to manufacture *madak* and *chandru* for smoking purposes outside the opium-selling shops; (2) the large quantity of opium, five tolas or 990 grains, which can be purchased and possessed, by one person without infringing the present law; (3) the indifference, even marked aversion, of the local authorities to carry into execution the spirit as well as the letter of the present law. Until these defects in the law and its administration are remedied the opium-smoking habit will go on increasing as before; indeed, if we are not misinformed, the habit will spread more rapidly though less observably than under the old rules of public and unrestricted consumption. HOBIDAS VEHARIAS, one of the Hindu members of the Commission, refers to this absurd state of the law as follows:—"There were some cases before the Presidency Magistrate of Bombay, where the accused were acquitted only because there were in a house say eight persons, and the quantity of opium used by them for smoking did not exceed the

total of what each of them was allowed, by law, to possess. This is in my view plainly ridiculous. Under the present state of the law, the opium-smokers can indulge in their vicious practice with impunity.

To remove this difficulty a strict law should be made prohibiting opium smoking in any form and under any circumstances, and thus frustrating the attempts of lovers of opium-smoking as well as those interested in the opium trade to escape from its clutches." If the government of India is desirous of maintaining its rightful ascendancy and control over the local Governments of the Empire, it must put forth a speedy and strenuous effort to check the utter disregard of Imperial orders now so shamefully exhibited in the provinces of Bengal and Bombay regarding the opium-smoking regulations. And if the Imperial Government is not to be charged with manifest hesitating and lack of moral rectitude, it must modify the law, reduce the quantity of opium saleable to any one individual, and enact that the manufacture or preparation of *madak* and *chandru* in any form, in public or private, for smoking purposes be absolutely prohibited everywhere throughout its dominions. The Government of India has already said that "the policy initiated in the Punjab (closure of *madak* and *chandru* shops) is, on the whole, the right one to follow." Let the Government therefore shew by efficient legislative enactments that it has the courage of its convictions, and insist that these enactments shall be carried out in spirit and letter by the local governments concerned, so that they cannot and dare not infringe the law. When this is done, we shall begin to believe in the good intentions of the Government of India on this subject; for until it does so, every right-thinking person must hesitate to credit the Imperial Government with any serious desire to arrest the spread of the opium smoking vice within its dominions.

—C—

VALVE OF MEDICAL COMBINATION.

It must be a source of gratification to all interested in the progress and social advancement of our profession to find how vigorously its members are grappling on to the fact of there being much strength in united action. Until within very recent years medical men appeared to have had a vague belief—practically a disbelief—in the good old dictum that unity is strength. They formed indeed a very disunited brotherhood. They have all, naturally enough, been one in the wish that the members of our profession be accorded every reasonable recognition and advantage; but they did nothing in common to bring about the fulfilment of that wish. On the other hand, as times have been growing harder and harder, there have come amongst us an increasing number of those who are willing and prepared to scatter to the four winds all the time-honored ethics which guarded the dignity of our calling; who are perfectly indifferent as to whether governing councils and bodies recognise them as belonging to the true fold or not; and whose sordid principles render them incapable of taking any other but a financial measure of the success of science. This war and disunion in our own camp having of late become seriously undermining to our constitution, the profession has come to see the necessity of rousing itself to

self-defence, and to find that the best security lies in determined and powerful union and association of its members against those unscrupulous ones who would sell their birthright for a mess of pottage. Medical unions and associations have now become the order of the day; and they have been actively engaged in protecting the interests of the profession, and in obtaining for its members many advantages and concessions which one or the other kept from them. The extent to which the poor are being robbed under the guise of extended charity by the establishment of pay wards; the disgraceful way in which medical men are being sweated, and allow themselves to be sweated by medical aid associations; the many instances in which women of ill fame and their vile abettors have involved reputable practitioners in most serious law suits; all these and a host of other schemes and ways which have pressed hard on general practitioners in particular have been, from time to time, put before our readers, and point to the necessity for medical organisation, and that the Incorporated Medical Practitioners' Association of London did not start a day too soon on its useful and active operations. Though this Association is but in its childhood, it has evinced vigour to raise the expectation that it will soon prove to be a power in the cause of general practitioners; and it is to be congratulated on its achievements and successes. These may be judged of from the report of the work done by the Association as detailed by DR. GEORGE J. EADY, in his valedictory address on returning from the office of President of the Association. Firstly, the Association is allowed, by several first-class offices for life insurance and for insurance against fire and accident, a large percentage off their usual terms. This commission being divided between the insuring member and the Association benefits both member and Association. Secondly, it has a department for the collection of long standing dues to practitioners. DR. EADY however recommends that a practitioner send us his bill for medical attendance immediately after cessation of attendance, and that fees be not allowed to accumulate. The Association has an Arbitration Department for the settlement of disputes between medical men. This saves the parties concerned from the publicity, inconveniences, delays, and large expenses, that lawsuits generally involve. The Association hopes to take the necessary steps for having the powers of the General Medical Council increased, so that that body may be empowered to cope with such evils as unqualified practice, practising after removal from the register, &c. A memorial has been addressed to the Council on the degrading effects of medical-aid and such like Associations, by which medical officers are over-worked and underpaid, while the profits of their labors go to the company engaging them. A Committee of the Association has been engaged in considering the matter of medical clubs for affording medical relief to the working classes. DR. EADY considers a medical club as the only way in which the working classes can satisfactorily procure medical assistance; but those who can afford a proper fee should not be admitted to the benefits of the club; and he thinks that the best way of removing the evils arising from the principles on which

medical clubs are now worked is for medical men to start and manage such clubs themselves, being principals, instead of subcontractors, this has been the suggestion of the Club Committee of the Incorporated Medical Practitioners Association. With regard to the management of hospitals, and the way in which they are thrown open to the public promiscuously, DR. EADY rightly deprecates the competition among the numerous hospitals to make their attendance lists as large as possible to favor their appeals for subscriptions; and he thinks moreover that there should be fewer special hospitals, and that these classes of cases should be treated at the special departments of the large general hospitals, thus affording students and future practitioners more extended means of acquiring knowledge in particular classes of cases. The Association devoted several meetings to the consideration of the pay wards system, and is of opinion that it is an improper application of hospital funds, and only needs a united and determined stand of the profession against it to have the system dropped.

From the foregoing it will be seen that the Association has been doing much in the interests of the profession. There appears unfortunately to be a tendency to multiply such Associations. Except for very good reasons, it is far better for the profession to be members of one large and powerful organization than for it to split itself up into small bodies working independently of each other. Each of such associations may do a certain amount of good, but their power and authority will not be considered sufficient by the State in any important representations they may make. What is required is one general union, and not local unions of the profession. We must concentrate our forces, and not scatter them more than special circumstances and considerations demand.

In India the profession has special and almost unique difficulties to encounter. There is much to be trampled down and much to be broken through, and nothing will come to us without agitation. That agitation to be productive of good must be strong, persistent, and determined; but it cannot be any of these except we *associate* and form a powerful band. We need not enumerate the many ways in which the private practitioners here are handicapped. The severe blows that officialdom levels at the private practitioner in India are unknown in any other country, and it requires a strong and representative body to voice these grievances in order that they may be minimised or altogether removed. There are matters too of great concern to the profession in general that demand consideration; but we must all speak with one voice. There is a message which we would wish to reach all of brethren in India; it is briefly this—*Associate*; and we hope that each and all of those whom it may reach will not fail to act upon the advice.

In his opening address at the annual meeting of the British Medical Association, London, Sir J. Russell Reynolds, drew special attention to the most striking fact of modern physiological, and therapeutical research—the power of living micro-organisms in the conservation of health, and the prevention and cure of diseases.

COMMENTS AND NEWS.

CELLULAR THERAPY AND THE SIGNIFICANCE AND MANAGEMENT OF FEVER IN CHILDREN.

CONSIDERING the pathology of fever and the close relationship of the morbid changes to each other, Dr. WILLIAM JACOBSON concludes that, whether in the animal or the plant, heat is the result of motion or activity which constitutes life of which the ultimate unit is the cell which suffers the same cycle of changes as the whole organism. Now in young animals, though the activity of the cell is very pronounced, still the cell is not stable and any impetus will effect it; hence children are more apt to grow feverish and readily attain a higher degree of temperature than do adults. Experiment has proven that toxins result from a variety of causes: from the life and growth of micro-organisms, from the microbes of contagious or infectious diseases, from the air we breathe, the food we eat, the water we drink, and even from the natural processes of fermentation in the alimentary canal. Now as soon as these toxins enter the circulation they attack the tissues and cells, and while seeking to demolish them, irritate them into extra action for the secretion of natural antitoxin to defend themselves, and then begins a tussle for the survival of the fittest. In this struggle there is considerable loss by cell metabolism and degeneration dependent on the quantity and quality of the toxin and the resistance of the cell. The amount of energy produced by this fight for life is represented by the heat generated, and this heat is measured as 'so much fever.' Therefore fever, is the result of a conservative action of nature, and so long as its activity is maintained, the cell will still respond; but over-stimulation paralyzing it it ceases to react and losing its energy and motility it generates less heat, producing a subnormal temperature, as illustrated in the exhaustive stages of some diseases. Though he has nothing to say against the employment of antipyretics, antiseptics, disinfectants and germicides in some cases of fever, still Dr. JACOBSON thinks that the attempt to subdue fever directly merely for the sake of lowering the temperature is opposed to the laws of nature, and worse than useless in contagious diseases in which something is wanted that will neutralise the poison, kill the bacilli or other microbes by its own toxin, and rid them from the system. Viewing fever as a condition of toxæmia, he strongly advocates assisting nature to overcome the poison and remedy the fever by subcutaneous exhibition of nuclein $C_{12}H_{10}P_2O_{11}$, which being developed through the principle resident in the nucleus nucleolus &c. from the absorptive products of digestion is furnished by the leucocyte to the various cells of the body to enable them to resist attack and destruction. If the cell contain sufficient nuclein to resist the onslaught of the micro-organism, the latter is deprived of nourishment and poisoned by its own toxin. The toxic products are then naturalised by the nuclein. The cells proliferate, the circulation is increased, and there is an efflux of the polynuclear white blood-corpuscles, which carry more nuclein to reinforce the cells and enable them to neutralise the toxins and envelope and imprison the micro-organisms, which, being thus deprived of nutrition, succumb to starvation and their own toxins and are carried off and devoured by the phagocytes, which are furnished with sufficient nuclein to neutralise any remaining toxin. It follows therefore that if natural immunity is caused by enough nuclein in the body, acquired immunity may be obtained by causing an increased production of nuclein, and by directly introducing nuclein into the body. This has been proved by FREEMAN,

who vaccinated with bouillon cultivations against small-pox; by RUMPEL, who aborted typhoid by injecting the dead bacilli of blue pus; by FORD, who showed that blood was able to destroy health; by BUCHNER, who settled that the direct antitoxical action of antitoxin neither took place in vitro nor in the animal organism, although the injection of any proteid, foreign to an animal organism, did increase the antitoxic power of the blood, and KLEIN and many others have been compelled to admit that the various anti-toxins acting merely as stimuli to the chemical processes of the cells, their real therapeutic value lay in the quantity of nuclein they stimulated; the production of and the greater the increase of nuclein the more powerful the antitoxin.

WHAT OTHERS THINK OF THE OPIUM COMMISSION REPORT.

THE *New York Medical Record*, in commenting on the very favorable report of the Royal Commission on opium and of the more or less unanimous testimony of the one hundred and sixty-one official medical witnesses to the effect that "the temperate use of opium in India should be viewed in the same light as the temperate use of alcohol in England. Opium is harmful, harmless, or even beneficial according to the measure and discretion with which it is used" expresses fear that such views will do a very great deal of harm. We have no doubt but that much evil will result from this supposed good—opium. Medical officials fear nothing in India, except their official superiors, and to this fact is to be principally traced the severe responsibility they have incurred in being instrumental in the Parliamentary promulgations of ideas dangerous in the present to opium-consuming races and dangerous in the future to mankind in general. With regard to the alleged beneficial effects of opium on such of the Indian people who use the drug, our contemporary remarks that the "question whether the race would not, on the whole, be better if no opium were used, is not answered". True, and what is more to the discredit of the bulk of the medical evidence at that Commission is, that it piled up a whole host of wild assertions altogether unsupportable, and theories wholly untenable. The evils which all this medical evidence before the Opium Commission will bring about will long remain difficult or impossible to correct; and future generations will point to the "experiences" of the Indian medical ages of 1893 as the root of it all. Our contemporary concludes: "So far as Caucasians are concerned, we cannot too emphatically assert that the Commission's conclusions do not apply at all. The use of opium is a distinct evil. Its moderate use is impossible; there are practically no temperate opium users. The opium eater always wants more and continues to want more until he is physically and mentally a wreck." But India under an official autocracy is unique in many respects, and she can knock all experience to atoms in support of her own favorite schemes.

THE SANITATION OF CALCUTTA.

IN reply to a series of questions put him by BABOO NOLIN BEHARY SIBCAR, one of the members of the General Committee of the Calcutta Corporation, Dr. W. J. B. SIMPSON, the Health Officer, wrote to the effect:—(1) Science does not explain why small-pox should appear periodically in epidemic form, or why it should be most severe in any one particular year, and the last epidemic is characterised by a periodicity which manifests itself every 4 or 5 years in Calcutta. (2) Since 1889 there has been a large tendency to increase in the mortality from fevers (from 3,307 deaths in 1889 to 3,667 in 1894) which is due to defective sewerage and other permanent insanitary conditions in Calcutta. (3) There has not been a single case of typhus fever between 1891 and 1894; but there have been 25 deaths from typhoid fever in this period,

and the most of these were hospital cases. (4) The susceptibility to Bubonic plague, according to races, was Chinese, Japanese, Hindas, Malags, Jews, Paris, English. The mortality which varied from 80 to 97 per cent. is the highest known in any disorder, and the disease, though slow in travelling, has a rather short period of incubation, so that there is little or no danger of its coming by sea to Calcutta, which takes a three-weeks voyage from China—if infected vessels were carefully disinfected. (5) Once the disease did get to overcrowded and soil-polluted Calcutta, either by land or water, the people would fall an easy prey to its ravages, while quarantine would be worse than useless. (6) Until overcrowding is prevented by a Building Act and immediate and radical measures taken to purify the soil and air by non-leaky and *effective* drainage and sewerage, there is every prospect of the mortality running up to *considerably* more than it at present obtains.

THE CAUSES OF THE DISEASES OF WOMEN.

DR. CHARLES NOBLE states that there are about five causes of the diseases peculiar to women. First among these is imperfect development of the sexual organs. With this condition is associated imperfect bodily development, and neurones are particularly common in such females. Menstruation is attended with much pain, which is felt over the ovarian region for some days before the flow, or the pain is uterine (from imperfect development of that viscus) and paroxysmal until the flow appears. These conditions result from excessive school work, anemia, hard work, too early undertaken by the poor, and improper hygienic conditions. To these causes the *Medical Record* (from which we epitomize) adds infectious disease during childhood.

The second cause of diseases peculiar to women is gonorrhoea, the ravages of which are serious, leading to uterine, tubal, ovarian and peritoneal inflammations.

The third cause is septic inflammation following child birth. These sometimes prove rapidly fatal, or give rise to salpingitis, ovariitis and peritonitis, inflammation or abscess of the broad ligaments, phlebitis, &c.

The fourth is lacerations during childbirth. These lead to cystocoele, rectocoele, prolapsus uteri, &c.

The fifth is mechanical and chemical causes from constipation, errors in living and in dress, &c. The first of these leads to hemorrhoids, uterine and ovarian congestions, uterine retroversion, pelvic congestion and general deterioration of health. The others to pelvic disease and displacements of the abdominal viscera.

THE SANITARY IMPORTANCE OF CLEAN STREETS.

In spite of the assertion that there is no absolute proof that disease is caused by city dirt, FRANK P. FOSTER, M.D., points out that there is every reason to conclude that dust is a very potent factor in the increase of urban mortality, as scores of reliable authorities have proven beyond all question that many pathogenic bacteria flourish in filth and may be blown anywhere the wind listeth to start afresh their lethal ravages. Even were such not the case, the fact remains that the detritus of offal and all manner of disgusting abominations lying in the streets is pulverised by the city's heavy traffic, and the moment our windows are opened (especially in summer) the first gust of wind treats us to a meal mixed up with *silly* dust, not on the bill of fare, or, on our return from a walk in the city streets, we may carry into our houses some disgusting stuff or the starting point of some virulent epidemic, in the form of mud on our shoes or clothes. He therefore urges that clean streets being conducive to

human comfort and health and *filth* the *synonym* for disease and death, every member of the medical profession should take an active part in furthering good hygiene, and *especially* directing attention to the sanitary importance of clean streets. This *especially* as the power of the profession to influence public opinion is enormous and the power of public opinion to help or hurt public officials in their work is *still* greater.

DEAD MEN'S BROTH.

THE REV. HARRY JONES was one of those few clergy-men who took especial pains to enforce practical sanitation amongst the poor of his parish. Having in vain tried his level best to dissuade his parishioners from getting their potable water from a pump *inside* the graveyard of St. George-in-the-East (London) he hit upon the expedient of placarding the pump with the startling though really true inscription "*Dead Men's Broth.*" This had the desired effect and averted a good number of cholera casualties during that epidemic, during which, he says, there was such a panic that it is more than probable that some people were buried alive. He quotes one case where Sarah B.—alleged to be dead from cholera, was on the point of being carried off by the mortuary cart, for burial, when a neighbour obtained leave to rub the supposed corpse with mustard. This external stimulation resurrected Sarah B.—who lived for many years after. DR. JOSEPH ROGERS tells a novel mode of treating cholera in these trying times. Being called in to see a potman seemingly in *articulo mortis* and apparently hopeless, he had him turned on to his abdomen so as to lay a towel dipped in spirits down his spine. It was night and the man's sister held a candle and as soon as the doctor had placed the soaked towel on the potman's back ready to be stretched along it, the nervous girl accidentally set it alight and the blaze must have frightened away the cholera; for the man sat up and eventually recovered.

THE COATES MEMORIAL FUND.

It is very gratifying to find the subscriptions to the COATES MEMORIAL FUND have mounted up to the decent figure of Rs. 4,000. The Treasurer to the fund has been most energetic in canvassing the local profession of Calcutta and succeeded in raising about 2,000 rupees from our brethren in this city. The bulk of the balance has come from Indian gentlemen outside our profession, while Rs. 1,500 of the whole amount has been generously donated by H. H. the Maharaja of Darbhanga, in whose household Dr. COATES was physician for some time. Dr. FERNANDEZ deserves credit for his energy in raising this fund to so good a figure. We now appeal to our readers to send in their donations to this fund, big or small, they will be thankfully received and duly acknowledged.

Subscriptions to the COATES MEMORIAL FUND may be forwarded to Dr. LAWRENCE FERNANDEZ, 5 Lloyd Street, Calcutta, or to the EDITOR, *Indian Medical Record*. Mark your postal order "for Coates Memorial Fund." Many military and civil Assistant Surgeons and private practitioners who knew Dr. COATES well, will feel it a privilege to give something towards this FUND, and we invite them to send in their mite without delay. One rupee is not too little, so send it in. The *Record* desires to lead the way in its section of this FUND by a donation of one hundred rupees. Who'll be the next?

HOW DOCTORS ARE HONORED.

THE Journal of the American Medical Association thinks that British journals are the *lowest* croakers on the subject of our profession being hard used and rather set upon

or kept down. It thinks too that British journals croak not only too loudly but without good reason against medical men, without deserving State decorations, or being accorded some social distinction. Going as far back as the time of HARVEY, our contemporary shows how in society the *ecce hominis* has never been denied the doctor, while medical worthies have been the favorites of the rich, much favored by haireesses, the acquaintances and friends of the great men and women of their times; and even the chosen friends and companions of royalty. In all these respects American physicians, too, asserts our contemporary, have not been badly off. The condition of even the rank and file of the profession, we are told, is on an average a condition of comparative prosperity. In short, like other men, says our contemporary, the doctor is what he makes himself socially and otherwise.

THE SUBORDINATE MEDICAL DEPARTMENT.

In order to facilitate movements of troops and do away with the bitter cries of "short-handed" and "overworked" that frequently rise in time of war and other emergencies, the Indian Government has decided that, from 1st October 1895, the Surgeon-General with the Government of India will dispose of all questions concerning recruitment, training, pay, education, promotions, dismissals, resignation, and postings for duty of the Subordinate Medical Departments of the three presidencies: so that, instead of reserving as hitherto, each department for its own presidency, men from the Madras command can be sent to Bombay, Bengal or any place in Indian territories or so forth, but they will continue to be recruited under local examinations and arrangements, as well as educated at the Medical Colleges of Bengal, Bombay and Madras, as at present.

A SUCCESSFUL EURASIAN MEDICAL ADMINISTRATOR.

We quote from the *Anglo-Indian*:—"It must be satisfactory to all large-minded men, as it is peculiarly gratifying to men of his own race, to know that SIR JOHN TYLER, the Eurasian Inspector-General of Jails, in the North-Western Provinces, has made his mark in Jail administration—as most strong Eurasians have done, in almost every branch of the administration in which they have been allowed to find their own level,—and is extorting praise not only from individual officials who affected to sneer at the Knighthood he had won, but in the very organ of petty official humours, whose melodies are usually the echoes of Under-Secretariat twaddle, and even of lower latitudes in the official mould. It is pleasant to see yards of appreciative type bringing up the rear of sneers, which have been snuffed out by strength of character and greatness of purpose.

BILE AND BILIOUSNESS.

SOME interesting experiments have lately been made with regard to bile and biliousness. It has been generally maintained that as bile is poured out a little distance away from the pyloric orifice of the stomach, and as peristaltic action normally is in a direction away from the stomach, bile consequently seldom gets into the stomach. PROFESSOR HERZEN found bile however in 107 out of 142 tests of the gastric juice in a case of gastric fistula. PROFESSOR CONTEJEAN'S experiments on himself confirm the experiments of Professor HERZEN. Thirty to fifty drops of bile in three cubic centimetres of gastric juice will stop gastric digestion. Dr. J. HANDBOURN'S experiments confirm the view that bile retards digestion, but that a little bile is normally present in the stomach and does no harm.

THE FORMATION OF A MEDICAL PROVIDENT FUND.

THE scheme for inaugurating a Mutual Benefit Provident Fund for members of the medical profession in India, has been a long time under discussion, and it has reached the stage wherein formulated rules, bye-laws, &c. have been drawn up. The scheme is now in the hands of a well-known firm of actuaries who are prepared to launch it on behalf of the Indian Medical Association. It provides for all classes, and has assignments for life-pensions, annuities and death payments. It is practically an embodiment of many of the best worked modern schemes. Our readers have long expected the launching of this Provident Fund scheme, and we may now say confidently that it is within easy range of practical politics. Before incurring initial expenses of printing, circulating and the like, it is absolutely necessary that not less than one hundred members of our profession, of no matter what grade or standing, do notify their willingness to join such a fund on approving of its rules, bye-laws &c. We therefore ask our brethren to send us post cards with the following words together with their names and address clearly written on them:—

"I am agreeable to the formation of the Indian Medical Provident Fund and to join the same if I approve of the rules and bye-laws when published."

Make no delay and forward your post card addressed to the Editor, *Indian Medical Record*, Calcutta.

WHAT MAKES A GOOD MEDICAL JOURNAL?

THE question as to what constitutes a good medical journal is discussed by *Gaillard's Medical Journal* much in this way, viz: that a medical journal, like a rational diet must contain a variety of material. The journal that simply strives to be amusing and which treats medicine in a flippant manner is a failure; one that is devoted to scraps and fragments, prescriptions and therapeutic hints betrays a mental dyspepsia rather hard to cure; journals devoted to sectarian and official views cause mental and professional, anaemia; but a good medical journal contains both heavy and light articles—therapeutic hints for every day use and solid articles, describing medical progress. Such a journal must prove both interesting and helpful.

A GOAT-FLESH FAMINE.

A CORRESPONDENT, writing to the *Statesman*, complains that unless the Calcutta Municipality stop the wholesale prosecutions they have lately instituted and alter the elaborate plans laid down for abattoirs or themselves erect slaughter houses sufficient to meet the demand, there is every probability that Hindu butchers will go on strike altogether and necessary goat flesh become an abstract quality, as those persons who have been proceeded against for being owners of unlicensed slaughter houses not only belong to the lower class of Hindus, but are also too poor to command the capital (Rs. 700 to 1,000) necessary for the elaborate improvement that the Municipality wish them to make of their places of business.

AN ANOMALOUS MONOPOLY.

SAYS the *Anglo-Indian*:—"While entirely sympathising with Mr. ERNEST HART, the Editor of the *British Medical Journal*, in his reasonable protest against the assumption, by a mere official service, of the dignity of an independent profession, and the monopoly by this service of appointments, for which in the public interest better provision can be made, it is only fair to admit the existence of valuable local experience in India, of which better use may be made than is shown in the extract in which some sensible realist in the *Indian Medical Service* protests against the overdoing of scientific romance."

ALIVE AT DUTY.

Brigade Surgeon, Lieut.-Col. H. Temple Wright, so well known to our readers, is busy in his retirement. He got the following resolution passed at the recent meeting of the British Medical Association:—"That this meeting desires to submit a respectful suggestion to the General Medical Council that every medical officer whose name appears in the *Navy List*, the *Army List*, and the *Indian Army List* shall be considered to be still alive and at the post opposite his name."

SHORT ITEMS.

Many members of the Indian Medical Association are applying for their certificates of membership, who have not paid in their subscription. This must be remitted before the certificate is sent. The names of "paid up" members are being carefully and neatly engraved by our artist on the certificates. This will involve a little further delay.

'Dodging payment of the doctor' becoming too general a practice at Bagillt, Dr. William Parry brought an action against one J. V. Price for breach of contract, in that having engaged him to confine his wife, he had neglected to send for him when she was brought to bed, and now evaded payment of the contract, though its breach was entirely his own fault. His Honor the Bailie found for the plaintiff.

Never startle your patient by unexpected or abrupt action. Always give him time to prepare for any new treatment or medicine. When the physician makes a change in the drug prescribed or the treatment to be given, always let the patient know something about how the new remedy will taste, and what it is for, or what the new treatment is, and how it is expected to act.—*N. Y. Med. Record*.

Several reputable physicians of Calcutta are having their names inserted into an advertisement which appears in the native papers, as connected with a native pharmacy at 88, Harrison Road. We sincerely trust their names are being published without their sanction, and we now call upon them to prevent their names being so used.

The following students from India have obtained the diplomas of L. R. C. P. and S. Edin. and L. F. P. S. Glas., at the last examinations:—Mervyn Thomas Archiball of Madras; Parimakar Krishnan Chitale of Poona; Goolab Singh of Lahore; Cursetji Pestonji Popat of Bombay; Helen Lauder of Bombay, William Arthur McCutcheon of Lucknow.

The unification of the Indian Medical Services in the three Presidencies will shortly be carried into effect as part and parcel of the Army Reorganisation Scheme, and only awaits the formal sanction of the India Office. The three services will be amalgamated and will be worked as at present through the Surgeon-General with the Government of India.

The Patna Hospital under the able superintendence of Dr. Grace Mackinnon has moved into its new premises. The buildings stand on a high piece of ground, and are distinctly ornamental, besides being well adapted for the purposes they are intended for.

A writer in the *Indian Daily News* remarks that Dr. Ernest Hart's address on Indian sanitation is excluded from the *Transactions of the Indian Medical Congress*, recently published under the authority of its Indian Medical Service editors. This was loyalty to the Service, but not to India.

Telegraphic despatches, dated London, 28th Aug. inform us that the following honors have been awarded for the Wairi Expedition:—To be Companions of the Bath—Surgeon-Col. Spencer. Distinguished Service Order—Brig. Surgeon G. Davis.

Mr. J. Mayho of Jhansi wired the other day to the Editor, *Indian Medical Record*, "Where is the Pasteur Institute started by a private practitioner?" We replied we did not know. Where is it?

Roger G. S. Chew, M.D., C.M., M.A.C., formerly Sanitary and Chemical Analyst to the Municipal Corporation of Calcutta, has been appointed a Sub-Editor of the *Indian Medical Record*.

It is with exceeding regret that we have to announce the death of that well-known and popular dental surgeon, Sir John Tomes, F.R.S., F.R.C.S., who has passed away at the age of 80.

Surgeon-Lieut.-Col. Ranking has been elected Secretary of the Bengal Branch of the Pasteur Institute in India in place of Surgeon-Col. Harvey.

The Stewart prize of £50 has been awarded by the British Medical Association to Brig.-Surgeon. Lieut.-Col. Douglas Cunningham F.R.S. for his work in India.

The Surgeon-General to the Government of India, and the Principal Army Medical Officer, intend visiting Madras and Bombay for the autumn tour.

The Bengal system of selling pice packets of quinine at post offices is being tried experimentally in the district of the Delhi civil divisions.

At the last meeting of the Medical Faculty of the Bombay University, Surgeon. Lieut.-Col. G. Waters was elected Dean of the Faculty of Medicine.

The *Tribune* informs us that the library of the Indian Surgeon General's Office contains 112,000 bound volumes and some 150,000 pamphlets. Can this be so?

The *National Police Gazette* has been mulcted in the sum of \$50,000 as damages for libelling Dr. A. E. Davis and Dr. B. F. Parrish.

The *Indian Planter's Gazette* has warmly espoused the cause of independent physicians, and we are very grateful for such able championship.

Dr. Crombie's eulogistic remarks on Monsieur Haffkine, at a meeting of eight members of the Calcutta Medical Society, are published in all the daily papers of Calcutta.

Members of the Indian Medical Association, who have not paid their subscriptions, will oblige the Treasurer (Surgeon-Major H. C. Hodgkins, S.A.S., Medical College, Calcutta) by sending them in without delay.

Subscribers in arrears with their payments to the "Indian Medical Record" will oblige the Proprietor by remitting their dues as early as possible.

Current Medical Literature.

MEDICINE.

Tobacco Blindness.

During the course of a lecture delivered by him at St. Thomas's Hospital, Mr. J. B. LAWSON, F. R. C. S., said that there was no broad rule of thumb to define the limit of age of the smoker or the quantity of tobacco that could be consumed with impunity as what might be a considerable excess for one person may be a very moderate quantity for another, and smokers may be from any age from 7 years to 65 and upwards; but the majority of cases of tobacco amblyopia occur in persons over middle age, and while the disease is very rarely met with in cigarette smokers, it is occasionally found in cigar smokers, and is most common in those who smoke from 0.5 to 0.75 ounce per diem of "shag" tobacco. Men and women who begin to smoke late in life appear to be rather more prone to tobacco-amblyopia than those who commence the habit at an early age. Concomitant non-ocular symptoms, such as insomnia, dyspepsia, undue nervousness and mental anxiety &c., are generally present in case of tobacco-blindness, whose characteristic symptom is central scotoma, due to either disease or loss of function of the papillo-macular bundle of nerve fibres, which supply the region of the retina in which is situated the yellow spot, whose integrity is essential for distinct central vision. The peripheral vision remains good and the nerve-fibres supplying the other parts of the retina are generally unaffected. As to treatment, he suggests the immediate cessation of the tobacco habit and the improvement of the patient's general condition by a strict regime of diet, change of air and scene, genial companionship, and the careful exhibition of strychnine, iodides, phosphates and bromides, according as symptoms indicate.

Examination of the Chest.

As the result of numerous experiments made on spirometry, pneumatometry and thoracometry, OTIS notes that while in health the lung capacity of males and females between 16 and 40 years of age corresponds to 28 and 16 c.c.m., respectively, for every centimetre in height every one that falls below these figure would either breathe abnormally or have something wrong with his lungs. Any doubts as to lung disease can be settled by auscultation and percussion aided by measurement of the elasticity and capacity of the lungs while in repose and at full inflation. In early phthisis the lung capacity is generally much below the average, as though the expiratory power remains normal, the inspiratory is lessened, and in many instances where the general symptoms were very suggestive of phthisis, the fact of the vital capacity being up to or beyond the normal has given distinct evidence against lung disease and thus warned off errors in diagnosis and treatment. The spirometer shows the cubic containing capacity of the lungs, the pneumatometer their elastic power, and thoracometry consists in the measurement of one measurement made round the chest and back, on a level with the nipples, and a second one, 2 inches below the first. He gives a series of comparison tables obtained from healthy lungs, and declares that treatment and prophylaxis by lung gymnastics is too much neglected.

Cats and Diphtheria.

In a recent contribution to the *British Medical Journal* Dr. W. WILLIAMS, the present Medical Officer of Health to the Glamorgan County Council refers to the Shropshire epidemic of diphtheria (1889) which in all probability originated with three cats kept by Mr. B., a family man.

The symptoms noticed in these cats, all of whom died, were cough, expectoration, wasting, loss of appetite and inability to swallow. For reasons various, a biological investigation was not made of two of the cats; but Dr. WILLIAMS, who examined the body of the third feline, declared it to have died of extensive lung disease. Whether the illness of the children can be positively attributed to the cats would be hard to say; but it is more than probable that it was, as the cats were ill some days before the children and, while ill, were carried about and nursed by them. He states that ever since this occurred he always makes tender inquiries about the cats whenever he is called in to see a patient suffering from sore-throat or diphtheria, as he firmly believes that there is an intimate connection between infectious sore-throat and diphtheria, and cats are not over-particular as to the localities they visit when on the prowl.

Diver's Palsy.

SHARPLES attended on a professional diver, who used to descend to 200 feet when wearing the dress and helmet, but immediately after his last dive he fell unconscious, the moment his head gear was removed. On coming round he complained of shooting pains in his joints, sensory impairment extended through the legs and arms right up to the neck, while motor power was completely abolished, and the bladder and rectum were paralysed. A fortnight after, mucous rales and dulness were noticed in both lungs, and bedsores beginning to form, cystitis and rectal paralysis were present, but there was no knee-jerk on either side. The patient grew worse and worse, and he finally died with a high temperature, the result probably of septic absorption. Necropsy 36 hours after death showed cord, very soft and irregular diffident and other softening and inflammatory changes secondary to hemorrhage at time of onset, but no definite trace of hemorrhage nor anything in the lumbar regions to account for the paralytic symptoms present.

Graves' Disease and the Thyroid Gland.

HECTOR MACKENZIE argued that Graves' disease should be classed among the functional neuroses; for though morbid anatomy gave but meagre information it was apparent that the palpitation, tremor, rapidity of cardiac action, flushings, sweatings, &c., that characterised this affection gave it a place among nervous disorders, especially of sympathetic and ganglia; but GREENFIELD conclusively shows that the neuro-vascular phenomena of Graves' disease are due to the action of excessive or perverted thyroid secretion, consequent on essential degenerative changes in the structure of the gland, even though there may not be any vascular dilatation within the gland itself, and the changes may not lead to any manifest enlargement of the organ as a whole. This subject needs farther threshing out, and if the above theories prove absolutely correct, very different notions, than now obtainable, will be entertained of the treatment of this condition.

Acute Rheumatism.

BOURGET says that though it is quite useless in the gonorrhoeal form and of but little use in some other forms of rheumatism, still salicylic acid is the sheet anchor in acute articular rheumatism; but while the skins of the young have a greater power of absorption than those of elderly persons and of blondes than those of brunettes, a great deal of the absorptive power of the skin depends on the vehicle used to dissolve the salicylic acid. Fat is increasing and vaseline, or glycerine, diminishing or almost extinguishing this power. In the muscular and neuritic forms he has obtained excellent results by giving 0.25 grain of codliver's oil three times a day in combination with 4 grains (each) of phenacetine and salol.

Heat Strokes.

As they did not observe any rigidity of the heart or coagulation of the muscular fibres in several dogs that died after being made to breathe hot air and do work comparable to that of a marching soldier, LAFRAN and BIGNAUD conclude that although severe exercise does not necessarily produce heat-strokes, it strongly favors its occurrence, and that, heat acting directly on the nervous system and not by inducing coagulation of muscular fibre or auto-intoxication death, cannot be due to coagulation of myosin; for, were such the case, cooling the heart would not reinstate the contractions when the temperature was sufficiently high to stop the beating.

Infective Bronchitis.

DUFLOCQ relates some cases of disseminated bronchitis in which pneumococci were abundantly found in the sputum which, though profuse and ill-smelling, did not contain tubercle bacilli but a few colonies of *B. Coli Communis* were present and the prognosis was unfavourable. He urges bacteriological examination of these cases of bronchitis, whose symptoms resemble cholera in many respects, and which always present the same insidious onset, gravity and slowness of convalescence.

Bilateral Brachial Paralysis.

DURING a sixty minutes operation at the Bernhardt Clinic (Berlin) for double salpingo-oophorectomy, the subject's arms were forcibly held up and back. The pressure of the clavicles upon the transverse processes of the sixth and seventh cervical vertebra caused sensory cutaneous disturbances, and a double Erb's paralysis of exactly the same extent on both sides in which there was complete paralysis of the biceps, brachialis, deltoid and both the supinator muscles.

SURGERY.

Present Treatment of Urethritis in New York.

COMMENTING on the various systems of drugging employed, DR. RAMON GUITERAS concludes:—(1) That, though it is impossible to treat urethritis by any rule of thumb, and a successful method has not been discovered, specialists are better able to treat it than are general practitioners. (2) That the patient should be treated conservatively by diluents and astringents, and the symptoms manifested should control the treatment required. (3) The most successful way of treating a fresh attack is to employ injections, such as bichloride, potassium permanganate, and argentic nitrate, that altogether stop the discharge or reduce it to a 'moisture about the meatus'; but of all these the nitrate of silver is the most reliable. (4) The diluent contains five grains, each, of bicarbonate and citrate of potash and just sufficient citric acid to effervesce, while the astringent injection contains five grains, each, of alum, carbolic acid and sulphate of zinc and one drachm of glycerine to the ounce of distilled water. (5) A stronger injection is sometimes ordered of zinc sulph. grs. x, Lloyd's colorless extract of hydrastis ʒss, ad aqua ʒiv; or a stronger still, of zinc sulph. grs. x, plumbi subacet grs. xv, tinct. catechu ʒi, tinct. opii ʒi, aqua ad ʒiv (6). Regulate the diet carefully, adjust a suspensory bandage and the injections three times daily together with the diluent suffices to cure ordinary anterior urethritis. (7). In posterior urethritis the diluent plus grt. x of tinct. belladonna, to check tenesmus, is kept up and the injection is discontinued; but if the process is very acute the patient is put to bed and given two hot Sitz baths daily and placed on milk and Vichy-water diet, and his bowels kept regular. (8). If these fail, recourse is had to

irrigating the bladder and urethra with a five- to ten-ounce syringe charged with 1:5000 potassium permanganate solution or 1:8000 gradually increased to 1:1000 silver nitrate.

Injection of Olive Oil for removal of impacted Biliary Calculi.

D. E. M. BROCKBANK discusses the above subject with a view to commend the more extensive use of olive oil in the treatment of biliary calculi. The methods in vogue hitherto have been the crushing of the calculus either by padded forceps or a strong needle. The danger of these methods lies in rupturing the duct, with peritonitis supervening. DR. BROCKBANK uses either olive oil or oleic acid, (which is much stronger in action) warmed to G. S. F. and injects it into the gall-bladder by means of a special apparatus consisting of a funnel, 12 inches of drainage tubing, and a No. 10 or 12 Jacques catheter, which fits into the fistulous opening and is further secured there by cotton loosely packed around it. The patient upon whom this treatment was tried benefited very little from it, owing to very serious organic disease of the head of the pancreas, the cancerous mass occluding the entrance of the *ductus communis choledochus* and thus producing jaundice with clay stools, bile-stained urine and colicky pains over the right epigastric region, &c. On inspection a pyriform tumour was visible over the gall-bladder, extending from the 9th costal cartilage down to the umbilicus. Cholecystotomy was performed, after which the pain and jaundice disappeared, and the urine lost its bile pigment, but the stools remained white and clayey. Bile flowed freely from the fistulous opening. This state of things persisted. After 8 weeks olive oil was injected, but of course, for obvious reasons failed to benefit the patient.

A Case of Hepatic Colic cured by the ingestion of Olive Oil.

DR. ALFRED S. GUBB of Paris contributes a case to the *British Medical Journal*, illustrative of the efficacy of olive oil in the treatment of Cholelithiasis. The patient was a man aged 46, who presented the following symptoms:—Sharp pain in the gall bladder region, recurring in paroxysms for a week, confining him to bed. Associated with the pain there was sickness. There was no jaundice, but the stools were very light in color. Morphia injections were the only means of giving the patient relief. A residence of 6 weeks at the Engadine, with plenty of exercise, however, suspended the paroxysms of pain for a period of 8 months, after which the old symptoms returned, associated with intense jaundice. This condition persisted with intervals of 3 weeks for a while and then the intervals became shorter and shorter until he was never free from pain. Regulation of diet, &c. at this period brought about no relief. The gall bladder was greatly distended and tender to the touch, hard bodies could be felt through the walls on palpation. At this stage the ingestion of olive oil was tried as a last resort. The patient commenced with 5 grains of calomel at night, followed by a draught of 8 oz. of fine olive oil in the morning. The oil caused no nausea, and from the very first day the symptoms began to abate, the pain ceased, the motions became darker and the urine clearer. He was cured in a month and a year later there was no return of symptoms. Nothing could be felt in the gall-bladder.

Position in the treatment of Elbow-Joint Fractures.

IN BONNET's paper before the American Surgical Association, statistics of 24 experiments in treating elbow-joint fractures were analysed. Out of 86 surgeons, 73 for the fractures

with the arm flexed at an angle of 90°, while 15 surgeons prefer the extended position. The two chief causes of failure are: (1) Limitation of motion, and (2) reversal of the normal humero-ulnar angle.

Fractures of the Internal Condyle.—In the position of acute flexion with downward and backward pressure in front of the inner condyle with semi-pronation, the parts came into good position. In the extended position it was found very difficult to co-aptate the fragments. In one case, they were widely separated and dangled loosely.

Fracture of External Condyle.—Acute flexion of elbow serves best to replace and retain the fragments. Extension admits of radius moving forward and swinging external condyle with it flexion is therefore impossible.

Transverse and "T" Fractures. The best position was found to be acute flexion with semi-pronation. Extension failed to hold the fragments firmly together.

Fractures of Epicondyle.—Good results obtained with either acute flexion or extension, though the former is preferable to ensure complete fixation. The paper was closed by Dr. H. L. SMITH pointing out some half dozen conclusions deducible from a consideration of the foregoing.

The Danger of Ear-Piercing.

At a coroner's inquest very recently held at Hackney over the body of a child who had died from septic or other allied form of poisoning after having her ears bored for ear-rings the jury severely censured the pawnbroker, from whom the ear-rings had been purchased, for attempting to pierce the child's ears, as they thought that it was not proper for anyone but a medical man to perform this operation. A medical contemporary, while advocating for cleanliness and admitting that a dirty wire in the ear, or an unclean pin or needle breaking the skin surface, might lead to very ugly consequences, contends that that jury had no right to hold medical men are alone capable of this office, which is not a work requiring high professional intelligence or skill, as for generations past ears have been pierced and more serious operations, such as circumcision, have been performed by careful and intelligent laymen, duly skilled in their particular office, with notable success, and an accident such as the above is relatively rare. A wound—cleanliness, being the only safe combination and the only safe rule, there is no need for over-working the medical men with petty jobs or for depriving those who do do them of their right to continue to do them, but local authorities ought to see that the person performing such operation should be careful, capable and scrupulously clean in both hands and implements.

Disease of the Oral Mucous Membrane.

As the mouth serves as a breeding place for the specific germs of many diseases, such as diphtheria, syphilis, tuberculosis, pneumonia, typhus, stomatitis, aphthae, thrush, glossitis, leucoma, leukoplakia, psoriasis, lechthyosis, tylosis, keratosis, plaques, opalines, &c., and there are very many cases on record where syphilitic infection has taken place from the oral cavity whose fluids instead of destroying it act as carriers of the syphilitic (&c.) germ, either by a kiss or a bite or carelessness on the part of the dentist, E. HERBERT ADAMS, Esq. M.D. C.M., D.D.S., complained before the Toronto Dental Society that too little attention was paid in the dental colleges to practical clinical instruction in the diseases of the mouth and the mode for perfect asepsis. He urges dentists to be particularly careful about thorough cleanliness in their instruments, and especially forceps, and in all doubtful cases of oral disease to refuse to perform dental operations until the mucous membrane of the mouth is free from disease, because by neglecting these precautions there is considerable risk to the

life of both the dentist and his patient, as it is quite possible (and has occurred several times) for unclean dental instruments to carry foul and fell diseases to a healthy mouth as also for the dentist to inoculate himself by scratching his fingers or knuckles on a patient's tooth.

A case of Double Penis and Imperforate Anus and Rectum.

Dr. J. J. COLE of Nashville reports that Mrs. T—at her sixth confinement, gave birth to a 10 lb boy with two well-developed male organs situated 6-8 inch apart on either side of the median line. The urethra bifurcating in the perineal region, the boy passes a good stream of urine through each penis, at the same time. Two raphe divide the scrotum into three pockets: the outer ones containing a testicle each and the middle resembling a testicle to the touch. The anus and rectum being absent, an artificial anus was made by Grosse's median incision, which the mother was instructed to keep open by dilating it 2 or 3 times daily with her index finger. The child did nicely, his bowels act as regularly as any child's, and he is in perfect health and developing into a fine little fellow—now over a year old.

Unjustifiable Surgery.

Mathews' Medical Monthly inveighs bitterly against the too hasty use of the knife. He illustrates two cases. One in which a malignant growth too far advanced to justify operative interference was removed by a certain Professor of Surgery, not because the operation would do any good, but simply because it would afford such a splendid clinic for his class. The other in which a lady had her womb, ovaries, tubes and two inches of her rectum excised because she had had a displaced uterus, accompanied by reflexes, which same could have been rectified by means other than extirpation. Declaring that there are fads even in surgery and that these soon die as do the patients, he strongly urges that a surgeon should be a man of firm convictions, but these convictions should be tempered with a feeling of pity for the afflicted.

Syphilis of the Lung.

SCHIBBEN finds that the diagnosis of this condition depends on the history of infection, syphilitic manifestation on other parts of the body, the result of antisyphilitic treatment and the absence of tubercle bacilli, as though it may appear as a phenomenon of secondary syphilis, still syphilis of the lung may exist without any other syphilitic manifestation, and while the physical signs most closely resemble tubercle, the symptoms present nothing pathognomic.

—10—

OBSTETRICS AND GYNECOLOGY.

The Rate of Growth of Ovarian Tumours.

As in the majority of these conditions, it is only by an accident that the patient learns, long (perhaps) after the damage has begun, that there is something radically wrong with her ovaries, Mr. J. BLAND BURTON, F.R.C.S., of the Middlesex and Chelsea Hospitals for women undertook to ascertain an answer to the momentous question—"How long has the tumour been growing?" Though not clearly definite as to the exact length of time, he places the ratio of the rapidity of growth of simple cysts, adenoma and dermoids arising in the oöphoron of the ovary as 1-9: 2-5: 2-25 and gives some interesting cases illustrating his contention that while adenoma and dermoid may arise in the ovary and attain dangerous proportions in an adult woman within the space of 40 and 86 months, respectively, a simple cyst grows with far greater rapidity and may attain as big, or even larger, dimensions within 17 months.

Treatment of Menstrual Dysmenorrhoea.

DISCARDING all other methods for mending the above condition, **ALANSON DICK Esq., F.R.C.S.,** of Cheltenham, *writes out a course of his own*:—Purging the patient *freely* twice a week, and currying the os at intervals of 3 or 4 days between the attacks, *slightly dilates cervix just before the period appears with a curved dilator, of his own pattern, after which he completely cures the uterine cavity and introduces one of his spiral wire stems, which he makes the patient continuously wear during the three or four subsequent periods and directs her to daily—period on or ceased, making no difference—syndring her vagina thoroughly with hot water.* He claims the spiral wire stems being fully open from top to bottom, they not only act as efficient drainage tubes in all manner of uterine affections, but can also be worn with safety and perfect comfort, whether the patient lie up or is up and about, provided she keeps herself clean by regular use of syringe or douche.

Accident caused by Curetting the Uterus.

THOUGH many authorities hold that the very common (and rather frequent) accident of running the curette through the walls of the uterus into the peritoneal cavity is harmless or has very insignificant consequences, **RAFFAY** records a case, recently, where death occurred, and **AUVARD** laying the blame of the accident to the method of dilatation employed, prior to curetting, insists that the curette, instead of doing the damage, merely discovers a perforation that has been already made, while among the ill consequences resulting from curetting **Dr. R. PICHVIN** enumerates:—(1) Abortion by the untimely use of the curette on a pregnant uterus; (2) various forms of septic infiltration and even death from careless antisepsis; (3) rupture of pyosalpinx or other collection of purulent matter necessitating immediate laparotomy or vaginal hysterectomy; (4) uterine atresia but very rarely. Whatever the actual causes, whether to want of skill or care on the part of the operator or whether to sheer accident, the probabilities for perforation are infinitely more when curetting is performed after a confinement at term or after premature delivery than when it is done after an abortion in the earlier months of pregnancy, and more especially when metal dilators with expanding blades are used. Diagnosis of perforation may sometimes be made erroneously owing to a sudden enlargement of the uterine cavity; but a correct opinion may be obtained by measuring the depth of the cavity at two or three different points.

Migrating Ovarian Tumour.

THREE years after the cessation of her catamenia, which had lasted from her 14th to her 48th year, a multipara, *æt* 51, consulted **Dr. HEYWOOD SMITH** for a right (?) ovarian tumour and said that 22 years back she had had ovaritis. Vaginal examination shewing a dextrally retroflected uterus, with a congested cervix and a pin-head polypus at the inner os; operation was resolved on, as she complained that too much walking caused her a great deal of pain in the right ovarian region with heat in the vagina. Abdominal incision shewed that the right ovary, which had atrophied to the size of a bean, lay, with its oviduct, deep down in the right side of the pelvis, from the left side of which the appendages were absent. The retroversion of the womb was caused by the fundus uteri being forced down and fixed by the left oviduct being stretched taut across the pelvis by the left ovary migrating over to the right side, while the fimbriated end of the left tube formed a hydrosalpinx, of the size of an orange, immediately underlying a smaller sized serous tumour (of the left ovary) which, besides being closely adherent to the omentum of the right side and the oviduct, contained cholesterol, hair and some bony plates. The ovaries, tubes

and fimbriae having been removed, the abdominal cavity was closed in three layers by *Swiss* tubes were not used. The uterus was only lightly fixed to the right on the 16th day after the operation; but six days later it resumed its normal position.

Tuberculosis at Delivery: Pueris Infected.

A WOMAN, *æt* 40, who had been *puerperal* for a long time, but in whom there was no clinical evidence of disseminated tubercle, or of meningitis, was delivered at full term by **F. LEHMANN** of a male child. Next day there was paralysis of the sixth nerve with stiffness of the nape of neck, and she died on the third day. The autopsy shewed widespread meningitis, a few tubercles in the omentum, and old tuberculous disease and miliary deposits disseminated over the lung substance; but the uterus and placenta were free from tubercles. The child died in 24 hours. There was serous effusion into its pleura and pericardium and echymosis of the latter, tuberculous deposit on the wall of the left ventricle; and the lungs, left kidney and the bronchial hepatic mediastinal mesenteric and lumbar lymphatic glands were distinctly tuberculous, but the peritoneum, brain, meninges, suprarenal glands and right kidney were normal.

Handy Needs for Post-Partum Hemorrhage.

DR. HIBST says if you fear *post-partum* hemorrhage, have ready:

- Basin of water, 120°.
- Vinegar.
- Broken ice—size of fist.
- Clean handkerchief.
- Hypodermic syringe.
- Ergot.
- Iodoform gauze.

1. If the hemorrhage comes, try, first, external stimulation, then bimanual stimulation.

2. Ice internally and externally. Throw either on abdomen.

3. Handkerchief soaked in vinegar squeezed dry at fundus of uterus.

4. Inject hot water, 120°.

5. Use a battery if you have one at hand.

6. Tampon uterus with gauze.

Having everything ready, you can cover all the remedies in a few moments. It is rare that you will have to go farther than combined internal and external stimulation. The intra-uterine gauze tampon will always stop hemorrhage, but should never be used except as a last resort.—*Medical World*.

Permanent effect of Hydrastinin in Metrorrhagia.

KALLMORGEN remarks that, while no doubt can remain as to the value of hydrastinin in metrorrhagia, reports are hitherto wanting as to the permanency of the results. He kept 86 patients of the Berlin Gynecological Poliklinik under observation during 1½ to 2½ years after treatment with the drug. The best results were obtained in cases of simple menorrhagia and of hemorrhage connected with retro-uterine hematocoele, previous abortion, or disease of the appendages. The success was less marked in chronic endometritis, very doubtful in hemorrhage during pregnancy or due to myoma, and nil in carcinoma.—*B. M. J.*

Birth of Child without rupture of Membranes.

FORBES cites the case of a woman *æt* 22, 7 months pregnant, who during an attack of pleuro-pneumonia gave birth to a child during the act of defecation. There was only a single pain and no hemorrhage. When **FORBES** was called in he found a large cyst occupying the vagina and bulging out between the thighs. He performed a *clitoridectomy* and removed

about a pint of amniotic fluid. The child was a female and weighed 5 lbs 8 oz, being 14 inches in length. The cord was very gelatinous and 16½ inches long, and was pulseless when in the vagina, but after active measures the child breathed well and took the breast. It lived only 16 hours, and the mother had a bad attack of empyema. Judging from the position of the ovum outside the vulva, the breech must have presented, and the placenta attached very low down without being actually *previa*.—B. M. J.

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Gynaecomastia.

H. STIDA maintains that though this name may be applied to the outward appearance of the male mamma in such cases, it does not imply any real histological resemblance to the secreting female breast as depending chiefly on a hyperplasia of the connective tissue, which encroaching on the neighbouring fat implicates both the fatty and the glandular tissues, and short processes or pouches can be made out in the tubular ducts; but the gland does not become acinous as in the secreting female mamma.

The Power of the Jaws.

HAVING ascertained by a spring machine fitted with a registering device that the stress required to crush a beefsteak was from 40 to 50 lbs, while mutton chops needed 35 to 40 lbs, broiled ham and roast beef 40 to 60, pork chops 20 to 5 and tid bits of cold boiled beef tongue 3 to 5 lbs, whereas the tougher parts of beef and mutton required a crushing force of 90 lbs. Dr. G. V. BLACK tried the crushing power of the bites of 150 people and found that in the habitual chewing of food a force was exerted varying from 20 to 30 pounds in excess of what Nature demands. A little girl of 7 years of age turned the index as 30 to 45 lbs, but a physician of thirty-five years of age registered over 270 lbs, at one crunch of his molars.

The Mechanism of Immunity.

MESNIL contributes the results of investigations into the question of immunity with especial relation to the part played by eosinophilic cells in the process. The subjects of the experiments were fishes, esp. *Gobio fluviatilis* and *Perca fluviatilis*. He found that the microbes (anthrax), which were inoculated into the peritoneal cavity, always end by being taken into the interior of leucocytes and there destroyed. According to his experiments the microbes, when in the interior of the cell, are still living and virulent; upon this point he gives details of experiments. In the case of the perch, at no time were eosinophilic cells found either in peritoneal fluid or in the blood, and this both before and after inoculation. It is, according to MESNIL, therefore certain that in this fish destruction of micro-organisms cannot be brought about by bactericidal products secreted by eosinophilic cells. The work is of considerable importance from a scientific point of view, and support the view on immunity already enunciated by METCHNIKOFF.

Pathology of Infantile Paralysis.

While describing a case of acute anterior poliomyelitis occurring in a child of five months of age, but previously healthy Dr. E. REEDLICH noted that instead of being confined to the ganglion cells (the popular view) the inflammatory process had chiefly affected the anterior horns of the spinal cord, whose entire length, however, had the appearance of the presence in the blood of some toxic element that materially affected the vessels and secondarily the structures of the spinal cord and also involved the remainder of the grey matter, while small foci of inflammation were found in the tracts of the white matter,

in the medulla oblongata and in the basal structures; but not in the cortex cerebri. The changes in the anterior horns were most intense in the lumbar, less so in the cervical and least in the dorsal region; but in the posterior horns, the central substantia gelatinosa, Clarke's columns, and in the anterior and lateral tracts of the white matter were found small 'areas of inflammation,' only one of which was discovered in the posterior column. The vessels outside the cord and especially the artery of the anterior fissure were affected with acute inflammation. The peripheral (especially the phrenic and inferior laryngeal) nerves showed very severe degeneration of the muscles. The inflamed areas in the white substance depended upon acutely inflamed vessels which, though in their vicinity did not appear to be connected with the anterior horns. The case terminated fatally on the tenth day after the onset of the illness, during the continuance of which there was loss of voice and knee-jerks, slight sensory impairment, feverishness, weakness of all the limbs and difficulty in swallowing and breathing.

Microbic Association in Tuberculosis.

MARAGLIANO would explain the varying course of phthisis in different subjects by the absence or presence of micro-organisms other than the tubercle bacillus. For him the tubercle bacillus is responsible for the tubercle nodule solely, and for a certain diminished resistance of the tissues created by its proteins or its toxins, and so rendering them more susceptible to the attacks of other micro-organisms. It is to these latter that we owe the pneumonic and caseous foci so frequently found in the course of phthisis. Unless other micro-organisms come, it may be that the tubercle bacillus may give rise to no symptoms during life, and occasionally one finds *post-mortem* tubercle nodules where there has been no suspicion of phthisis during life. Most of the secondary symptoms of phthisis—for example, fever, wasting, bronchopneumonia—are, according to the author, due to the superposition of micro-organisms other than the tubercle bacillus; and it is just because the air of mountains and of the sea is so free from these organisms that it is so negatively beneficial to the phthisical. This conception of mixed infection in phthisis was broached by the author in 1891, and seems to throw light on the clinical course of pulmonary phthisis.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Criminal Anthropology.

In a recent essay on this subject Professor LOMBROSO, of Turin, describes what he terms the "criminal type." The features characteristic of this type are found in the faces of most regicides and assassins of presidents, notable Fieschi, GUITEAU, and NOBILING. To this type belong also the promoters and leaders of reign of terrors, such as CARRIER, JOURDON and MARAT. Among noted anarchists he describes the bomb thrower, BAVACHOL. LOMBROSO says: "What first forcibly impresses the beholder of BAVACHOL's face is its bestiality. Its asymmetry is strongly marked; the nose deviates greatly to the right, the ears are implanted on the head at different heights, and the lower jaw is heavy, square and prognathic. In speaking of BAVACHOL's history, he says: "The pupil of a primary school until the age of fifteen, BAVACHOL left it almost absolutely illiterate. Designed by his parents for a simple mechanical trade, he abandoned his apprenticeship, because unable or unwilling to acquire even its rudiments. He became a hopeless idler,

diamond shafts and circled counterfeit money. He murdered a corpse and robbed it of its jewels. He murdered an old hermit of eighty-four years, in order to steal his money. At about the same time, he attempted to kill his mother for a fancied offense. It was established during BAYACON's trial that his grandfather, KOENIGSTEIN, and his great-grandfather both perished on the scaffold convicted of murder and arson.—*Alienist and Neurologist*.

Legal Penalties for Medical Negligence.

THE VIENNA Medical Chamber at the present moment has the following question under its consideration. A poor law medical officer having been called to see a man who had fallen ill with gastric symptoms, he diagnosed acute alcoholism without making any examination, and prescribed soda-water with cold cataplasms. The condition of the patient became worse, and another practitioner, who was sent for, found him unconscious and apparently in a fit of apoplexy. The patient died, and a charge of causing bodily harm was brought against the original medical attendant, in accordance with paragraph 481 of the Penal Law. The expert who gave evidence explained that although a careful examination might not have led to a different diagnosis, there was, in his opinion, a neglect of duty, for the poor law medical officer had not fulfilled his obligation of trying to find out the cause of the illness. The accused was fined 25 with twenty hours' imprisonment, a sentence which was confirmed by the Court of Appeal. By this decision the court declared that the neglect of examination had caused no injury to the patient, but that the medical officer ought to have known that his conduct might endanger life. This result has caused a great sensation throughout the profession of medicine, for it throws serious obstacles in the way of medical treatment. Who would perform a surgical operation if the above-quoted paragraph be interpreted in this manner? Every operative procedure exposes the patient to danger, and the surgeon will have to justify himself even in the cases where operations are successful. The law punishes the infliction of bodily injury by a medical man's ignorance or negligence, but does not punish the endangering of the patient's life or health when caused either by medical treatment or by neglect. The Medical Chamber has taken up this question, and at the last meeting a member brought in a motion referring to the provisions of the law as regards offences committed by medical men. Paragraph 481 is inapplicable hereto, for it imposes penalties amounting to £40 fine or three months' imprisonment, whereas paragraph 488 imposes only a fine of £40 in the case of actual injury or death due to neglect. The Chamber adopted this motion, and will take steps to defend the profession against decisions which are not in conformity with the spirit of the law.—*Lancet*

Disinfection of Rooms.

CONSIDERING the important part played by disinfection in tuberculosis and the cumbersome modes hitherto employed for its effect, DR. SHERIDAN DELÉPINE, discarding other media, argues strongly in favor of bleaching powder, in solution, as being the cheapest and yet the most efficient disinfectant known, as beyond its well-known bleaching action on all organic odors and neutralisation of mineral pigments, chlorinated lime does not spoil things as much as one would expect, and can be used without any fear of damage in rooms from which all hangings and carpets have been removed. He advises (1) whitewashing the walls, ceiling and floor with three or four coats of a ten-per-cent aqueous solution of bleaching powder. (2) A large tin basin filled with water or chlorinated lime solution and carrying water-bath fashion

(either floating in it or almost closing the mouth of a glass vessel containing acetic acid or mercuric acid, the basin being placed on a small earthenware stove in the middle of the room to prevent draughts from being lighted and the doors and windows closed as well as possible. The steam, as it rises, supplies the necessary moisture, while the acid vapor secures the acidity of the air required to cause a more rapid and continuous setting free of chlorine, which thoroughly effects the work of disinfection at a very low cost.

The Dietary of European Peasants.

DR. A. THUBMAN, in the *Anthropological Review*, published at Milan, gives an interesting summary of the dietetic habits of the rural population of several European countries as follows:—

Belgium.—Coffee, black bread, potatoes, vegetables, chicory and sometimes *salsimens*.

Holland.—Black bread, vegetables, fish, coffee.

England.—Beef, pork, potatoes, vegetables, tea, cheese, beer, cider.

Ireland.—Oatmeal bread, potatoes, milk, a little lard.

Scotland.—Oatmeal bread, potatoes, milk, butter, coffee, tea, very rarely flesh.

Pomerania.—Potatoes, milk, green vegetables, lard, flesh three times a week.

Rhenish Prussia.—Milk, soup, dried fish, potatoes, flesh for the feast days.

Saxony.—Bread, butter, cheese, soup, vegetables, coffee, flesh on feast days.

Bavaria.—Porridge, butter, milk, cabbage, potatoes.

Italy.—Macaroni, bread, fruits, beans, peas, and lentils, wheat, rice, wine, a little flesh on feast days, but only in certain regions.

Spain.—Bread, vegetables, fish, fruits, flesh as a luxury.

Russia.—Rye bread, cabbage, mushroom soup, wheat cooked with milk and oil.

Sweden.—Potatoes, rye, oatmeal, barley, milk, salt herring, beer, no flesh food.

Switzerland.—Cheese, milk, coffee, vegetables, soup, wine, rarely flesh.

Turkey.—Black bread, onions, *poivreux*.

France.—In the neighbourhood of Bourgogne meat is eaten but once a year. The peasants of Morvan eat meat twice a year. The peasants of Sarthe once a year; the peasants of Auvergne five or six times a year; the Bretons never, except rich farmers, who eat flesh on feast days.

We see from this table that European peasants subsist almost wholly upon vegetable food, a regimen which is highly economical, and by which they are sustained in good health.—*Good Health*.

A Good Health Prescription.

My palld friend, is your pulse beating low?
Does the red wine of life too sluggishly flow?
Set it spinning through every tingling vein,
By outdoor work, till you feel once again
Like giving a cheery school-boy shout;
Get out!

Are you morbid, and, like the owl in the tree,
Do you gloomily hoot at what you can't see?
Perhaps, now, instead of being so wise,
You are only looking through jaundiced eyes;
Perhaps you are bilious, or getting too stout;
Get out!

Out in the air, where fresh breezes blow
Away all the cobwebs that sometimes grow
In the brains of those who turn from the light
To all gloomy thoughts instead of the bright
Content with such foes and yet them to trust
Get out!

—*W. A. R. R.*

TERAPEUTICS AND PHARMACOLOGY.

Methylene Blue in the treatment of Filaria sanguinis Fovinis and other Affections.

A. In a recent meeting of the Fifth District Medical Association, President **AUSTIN FLINT**, M.D., LL.D., explained that a leak having in some peculiar manner sprung from the lymphatic into the urinary tract, the *Filaria* passed from its familiar haunts in the lymphatics of the scrotum and nether extremities into the rest of the lymphatic system where, growing into 0.84 millimetre long, and 0.0075mm broad with a pointed tail and a rounded-off head carrying a tongue-like process, it carefully hid itself till its victim sought his couch for sleep when it sneaked into his blood and gave rise to chyluria, hæmaturia and chylous diarrhoea. In *plasmodium malaria* methylene blue acts almost like a charm, while 2 grains given every 4 hours for less than a fortnight totally cured a case where besides numerous *filaria* being found in his blood, the patient's urine (sp. grav. 1021.5) was devoid of urinous odor, presented a white opaque color (like milk) with a very slight reddish-yellow tinge and acid reaction. It contained 1.51 per cent of urea, 39 per cent. of albumen and a whitish sediment mixed up with fatty granules, red blood-corpuscles, oil globules, leucocytes and bacteria; but not so much as a trace of sugar. Equally satisfactory results were obtained in malarial splenitis and chronic cystitis with this drug; but, it was in gonorrhoea that it seemed to exert such a specific action (even though it colored the urine and faeces a greenish-blue for a few days) by immediately attacking and destroying the gonococcus, that Dr. FLINT declares, immoral though his suggestion may at first sight appear, and improper it is nevertheless a scientific proposition that methylene blue would probably act as a prophylactic against gonorrhoeal infection in impure intercourse.

Calcium Chloride in Snake-bite.

CALMETTE'S contention that the therapeutic action of calcium chloride lay in its forming some substance which entering the circulation either neutralised or destroyed the snake poison, is rejected by PHISALIX and BERTRAND who claim that if this salt is to be used it must be injected deeply at the exact spot where the fangs enter; as its action is purely local and it destroys the poison, locally by causing the tissues to slough and thus preventing absorption of the toxic material.

Opiate Grass.

In certain parts of New Mexico small patches are found of a grass which produces a deep sleep on any animal grazing on it, and travellers have often been seriously inconvenienced, when they have accidentally halted near a place, where this grass grows pretty thickly, as their horses after grazing on it have fallen fast asleep and they were unable to continue their journey. A question has arisen as to whether this grass contains opium or whether its narcotic power is due to some other substance.

Gall-Stones treated with large doses of Olive Oil.

A WOMAN, at 46, complaining of biliary colic with severe vomiting, vomiting, collapse and acute pain extending from

liver to right shoulder-blade hypodermic morphine was resorted to ease the pain, but well-marked jaundice followed and passed off in a few days' time. Two months later she had another severe attack of colic, which re-appeared as intervals of 21 to 44 days for nearly 3 months. As gall-stones were not found in the stools and the usual remedies proved useless, cholecystotomy was advised by Dr. STEPHENSON, and the woman given 8 grains of bile pills, overnight, and next morning 3ij of olive oil. She passed 6 large gall-stones, two of which were faceted and measured nearly 0.5 inch. There was little, if any, nausea and no pain, and, the jaundice passing off in a few days, the patient made a complete recovery, and for the past year has been free from colic.

Morphinomania cured by Phosphate of Soda.

MANY, but most of them futile, methods have been tried for the removal of the above condition from the unfortunate slaves to the awful habit. A certain medical man used to use seven grains of morphia daily, so M. J. LEYS gave him sodium phosphate, subcutaneously, gradually increased in posology. As the phosphate was increased, the morphia was progressively diminished for two months, when it (the morphia) was discontinued entirely and the quantity of the sodium phosphate was daily decreased and finally stopped, in two weeks more. The desire for morphia has altogether vanished.

Value of Iron Preparations.

THE experiments of MARFON and HAMBURGER prove beyond doubt that iron, medicinally applied, is not at all absorbed by the human body, nor does it build up the blood hæmoglobin, which chiefly contains the iron (from 30 to 40 grains) found in the body. The only ways that iron can be excreted from the animal economy is per faeces or urine, but BRUNER, SCHMIDT and VOIT have established that while the body-iron is lost per the urine, the medicinally added iron, eliminated by this fluid, is inappreciable and as at the very least 99 per cent. of the ferruginous salt taken per *ore* comes away with the faeces, without being influenced by the stomach or the liver, the alimentary tract plays little or no actual part in their absorption. Therefore, argues Professor HUGER, the utility of iron in therapeutics is very largely a matter of suggestion; as, if this metal or any of its preparations be absorbed by the body, the quantity absorbed is scanty indeed and not necessarily assimilated; while on the other hand, in about ten days, the ordinary food will convey to the organism iron equal to one-third of that in the blood, as, by a peculiar ordinance of Nature, food always contains enough iron to supply the need even of the very anæmic.

Serum Treatment of Malignant Growths.

TOXITERAPY has of late taken some giant strides in various directions with varying success as to results, and now RAPIN claims that if pursued with energy and perseverance in most forms of malignant tumours, not readily amenable to

operation, repeated subcutaneous injections of streptococcal toxin, will produce temporary (if not permanent) amelioration and retard further growth by exciting in it a rapid degeneration which may extend even to necrosis of the growth and ultimately lead, in the most favorable cases, to a radical cure.

Tooth-Wash.

Label.

Fragrant tooth-wash, for cleaning and preserving the teeth and gums, imparting a refreshing taste and feeling to the mouth. Directions for use: Dip the brush in water (soft or rain-water the best), then pour a small quantity of the wash on it, and rub it on the teeth; it forms a froth (on the mouth,) which should be allowed to penetrate every crevice.

—Chemist and Druggist.

Treatment of Uræmia.

As the blood serum of healthy human beings and of those suffering from non-uræmic Bright's disease produced nephritis or glomerular nephritis when injected into dogs, while similar treatment with the blood serum, or the dropsical effusions, of persons afflicted with uræmia, developed artificial uræmia in dogs. HUGHES and CARTER made several experiments with human, dog and horse serum on rabbits, which not only shewed that the digestive tract was the seat of origin of the poisonous substance, whose formation might be prevented by a vegetable diet, but also led to the conclusion that while the nephritis-producing substance was constantly present in the serum of carnivora such as the human being and the dog, it was entirely absent from the serum of herbivora and graminivora, such as the horse. What the actual nature of this poisonous substance may be is still a matter of doubt; but its power can be considerably lessened and even destroyed by moderate heat. Vegetable purges and diaphoretic, blood-letting and hot-pack are suggested by Drs. CARTER and HUGHES as being the wisest course of curative treatment; but they argue most strongly in favor of venesection, which they say "cannot be too highly recommended," as its good effects are best seen in grave cases, such as marked dyspnoea, hyperpyrexia, cerebral symptoms, &c.; but the quantity, to be withdrawn, ranges from 20 to 40 ounces, and depends very greatly on the special character of the case.

Correspondence.

INSANITARY CALCUTTA.

From S. M. J. CLARKE, Esq.,

Secretary, Bengal Chamber of Commerce.

To THE SECRETARY,

Govt. of Bengal, Financial Dept.

SIR,—The attention of the Committee of the Chamber of Commerce has been directed, by representation from some of its members, to the highly insanitary condition of the Town of Calcutta. Vital statistics prove that the residents are not only liable to the endemic ailments of the East, but that those waves of disease, which modern science in many other places has worked so successfully to

stamp out, are recurring in Calcutta with greater frequency and increasing severity. After emerging from an alarming outbreak of small-pox, and from a period of anxiety from cholera, it is startling to learn that the residents have now to face another epidemic.

The community has learned from the remarks published by the Health Officer to the Municipality, that fevers of a typhoidal character are greatly on the increase throughout the city, and while it is satisfactory to know that the poorer classes of natives are not as yet subject to this form of malady, it is a matter of serious concern to be made aware that fevers of this type are increasingly prevalent amongst Europeans who inhabit the mercantile quarter. The insanitary construction of the city was demonstrated by MR. BALDWIN LATHAM a few years ago. The epidemics that have of late raged with so much deplorable virulence among all classes seem to declare the consequences of this position, the only inference to be drawn is that the inhabitants must be rendered liable to epidemic outbreaks so long as the causes of disease are permitted to exist, and, by their continued existence, to increase the danger.

I am here to point out that the Committee view with the very gravest apprehension the very serious consequences which would follow to this city were the plague to reach it from China. The scourge appeared not long ago so near as Singapore. There is reason to believe that if it once entered Calcutta the insanitary condition of the town is likely to give it a firm hold. The Committee consider that the probability of such an epidemic cannot be ignored. They would urge that precautions, other than those associated with pratique, should be taken to guard the metropolis against such a contingency as they have indicated. Were the plague to reach Calcutta, the immediate result would be the establishment against the fort of quarantine on a scale which would dislocate, and even suspend trade, and lead, not improbably, to financial disaster. Locally, the effect on labor would be fatal. There would be a general flight from the stricken city—a flight in itself likely to make the mischief infinitely terrible. With the possibility of such a misfortune, added to the increasing dangers of local insanitation the Committee, representing the mercantile community, feel they cannot keep silent.

The Committee have reason to believe there is a very strong feeling on the part of all sections of the community that efforts should be put forth by those responsible for the health of the city to grapple with its insanitary evil, and I am to say that as the Municipal Commissioners have failed to do so, the Committee consider the time has arrived when the Government of Bengal should lend its influence and help to rectify the state of affairs I have alluded to.

The Committee recognise and frankly admit the physical difficulties that beset the whole question, and acknowledge that the Municipal Commissioners are in no way responsible for inefficient works to which they may have become heir. For such they must be exonerated.

There can be no excuse, however, for the perpetuation of any dangerous nuisance that can be removed, nor can it be for a moment admitted that the Municipality have any

right to serve the public interests at their own discretion and without reference to hygienic necessities.

In this connection I am to direct attention to the trenching of night soil to the south of the city at Gergatsha in the midst of the populous suburb of Alipore. This has come to be an offence to the general community. It is known that trenching has been carried on there for many years, but of late it has out-grown in its proportions all ideas of decency. It has become so injurious that the Committee need not go into the character of the nuisance. That has been admitted by the decision of the Alipore Court and by His Honor the Lieutenant Governor in his recent minute on the subject. They confine themselves to condemning the extreme thoughtlessness and want of appreciation of consequences involved in locating what, under any circumstances, must inevitably be a nuisance at a point where it must be most intensely felt. They protest against continuing this trenching ground, and especially against the opening of a new ground on the windward side of the city, and, as the Municipality appear unable to appreciate the danger of locating a trenching ground in such a relative position to the city, the Committee would appeal to Government to take action under the controlling sections of Act II. of 1888 (B.C.) and to cause the Municipality to remove trenching grounds entirely from the windward side of the city, and to place them in a locality where their ill effects shall either produce no harm or produce the minimum of harm. Unless this is done, the opening of a new trenching ground will create a permanent danger to the health of the city, and especially to that of the southern suburbs.

The Committee would very earnestly solicit the favor of His Honor the Lieutenant-Governor taking this matter into early consideration and passing such orders as may be necessary. In the meantime, they would solicit from Government the favor of Government prohibiting the Municipality from opening any new trenching ground on the south or south-west of the city and the southern suburbs, and generally they would submit that a careful investigation should be made into the reported increase of fevers of a typhoidal character, and into the causes of such increase.

CALCUTTA, }
10th July 1895. }
I have the honor to be
Sir,
Your most obedient Servant,
(Sd.) S. E. J. CLARKE,
Secretary.

II.

From H. H. RISLEY, Esq.,

Secretary to the Government of Bengal.

To THE SECRETARY,

Bengal Chamber of Commerce.

SIR,—I am directed to acknowledge the receipt of your letter No. 851—'95, dated the 10th July 1895, in which the attention of Government is drawn by the Chamber of Commerce to the insanitary condition of the town of Calcutta, and to the facilities which are afforded by it to the introduction and spread of epidemic diseases. The trenching of night soil to the south of the city at Gergatsha is referred to as highly offensive, and as a standing menace to the health of the town; and the Chamber,

while urging that steps may be taken to discontinue the use of this trenching ground, request that the Corporation of Calcutta may be called upon to remove trenching grounds entirely from the windward side of the city, and to place them in a locality where their ill-effects will not be felt. It is also desired that a careful investigation may be made into the reported increase of fevers of a typhoidal character in the town, and into the causes of such increase.

2. In reply, I am directed to say that the Lieutenant-Governor welcomes the Chamber's representation as lending support to the action of Government in endeavouring to arouse the Corporation of Calcutta to a sense of their duties and responsibilities as guardians of the public health. His Honor fully agrees in the importance, on commercial as well as on other grounds, of improving the health of Calcutta, and keeping it free from epidemic. He has constantly dwelt on this, and impressed it on the Corporation; and the weight of the Chamber's influence will be of material help in bringing about the desired result.

3. As regards the disposal of sewage in the area, as yet unprovided with regular sewers, I am to say that the Lieutenant-Governor is unable to go with the Chamber in their general condemnation of the system of trenching sewage as such, nor can he admit the necessity of prohibiting the location of trenching grounds to the south or south-west of Calcutta. The practice of rendering sewage innocuous by mixing it with dry earth was hailed not very long ago as a great sanitary discovery, and it has been largely adopted in Europe. The Lieutenant-Governor is informed that the system is successfully followed in several towns in India, and it is the universal practice of Bengal jails to dispose of faecal matter in this way, and no unpleasant results have ensued. It is the misuse and not the use of the trenching system which should be objected to. It depends for its success on the oxidizing effect that a porous substance, such as dry earth, exerts by bringing any sewage with which it is mixed into intimate contact with the air contained in its pores. If crops are afterwards grown upon the land thus treated, the process of purification goes on more rapidly and certainly. It follows from this principle that sewage trenches must be shallow, and that the quantity of loose earth filled into them must be substantially in excess of the quantity of sewage to be covered. In the neighbourhood of Calcutta, where the rainfall is heavy and the subsoil water stands at a high level during several months of the year, special care is required in the management of a trenching ground. If the sewage is deposited too deep and thus removed from the influence of the air, it retains its offensive character for an indefinite time, and undergoes a process of fermentation which generates foul gases very dangerous to health. At the same time it is liable to be affected by the movement of the sub-soil water, and to pass by percolation into tanks and wells in the neighbourhood of the trenching ground.

4. Another essential part of the system is that a definite ratio should be established between the population to be served and the area to be reserved for trenching. It was the duty of the Health Officer of Calcutta to have calculated these figures, and to have shown that, given a

population of so many thousand persons, so many tons of fecal matter have to be disposed of daily. So many square yards of surface are required for this purpose, and therefore so many acres should be taken to ensure provision for the requirements of a year, after which it is assumed that if the soil has done its duty, the same area can safely be trenched over again.

5. The Lieutenant-Governor is satisfied that these necessary precautions were neglected at Goragacha in the old ground, and he is informed that they are being neglected in the new ground which adjoins it. Trenches have been dug six feet deep, and too much sewage has been deposited in them; some have been dug in low-lying ground where water will stand after rain has fallen; others have been dug in loose and freshly laid earth, which heavy rain will saturate and convert into a swamp. There has been no attempt to arrange the trenches symmetrically, so that different parts of the ground should come into use in regular rotation; nor have any crops been grown. No calculation appears to have been made of the amount of fecal matter to be disposed of or the area required for the purpose, and no attempt has been made to establish a proper relation between the population to be served and the area of the trenching-ground. The result of this neglect of the elementary conditions of sanitary trenching has been to convert the old Goragacha ground into an extended cesspool of the most offensive character, while the new ground will soon be reduced to the same condition, unless special precautions are taken.

6. Instructions will now be issued to the Chairman of the Corporation to the following effect:—

(1) In no trenching ground should the depth of the trenches exceed three feet, nor should the bulk of sewage deposited exceed one-half of the amount of earth filled in.

(2) Immediate effect should be given to this rule in dealing with the new Goragacha ground, and as soon as that ground has been used up, it should be closed, and the sewage of the wards concerned deposited in the new ground at Gopalpur.

(3) This ground, and any new ground that may hereafter be opened, should be trenched symmetrically and on a regular system, so that each part of it shall be used in rotation, and crops grown on the portions used as soon as this can be done.

(4) Trenching on low land should be avoided as far as possible: if only low ground can be obtained, it must be artificially raised.

(5) Steps should at once be taken for acquiring the necessary area of trenching ground, and a regular scheme should be drawn up for its working; the amount of sewage to be disposed of should be estimated with reference to the population concerned; and the area necessary to deal with it on the conditions laid down above should be accurately determined.

(6) The old Goragacha ground has been brought into such a foul condition that in all probability crops will not grow on it. If this is the case, it should be turfed over at once, and the new Goragacha ground should be either turfed or cultivated as may be found practicable.

7. In order to secure that these orders shall be effectually carried out, the Sanitary Commissioner will be request-

ed to cause all the trenching grounds near Calcutta to be regularly inspected by the Deputy Sanitary Commissioner of the Metropolitan Circle, and the result of his observations reported to Government.

8. The Chairman of the Corporation will be asked to report on the statement referred to in paragraph 2 of your letter, that fevers of a typhoidal character are greatly on the increase throughout Calcutta.

Yours, &c. H. H. RISLEY,
Secretary to the Government of Bengal.

CALCUTTA, 25th July 1895.

LEPROSY IN ITS PATHOLOGICAL AND CLINICAL ASPECTS.*

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Though elegantly got up and beautifully illustrated the above work unfortunately contains a number of errors, illogical deductions and deliberate perversion, or crowding out, of important public tests and solemn facts, for which peccadilloes it would be hard to fix the actual culprit as the author's views and the translator's ideas are inseparably jumbled up together.

I will not impinge on your time and space by critically treating each one of the many inaccuracies, but shall merely confine myself to some of the most glaring and unpardonable blunders:—(a) page 1. "Leprosy is a chronic disease caused by the lepra bacillus," because the microbe is only found in the latter stages of nodular leprosy and is utterly absent in the early and middle stages, and in the anæsthetic forms of the disease. (b) page 25. "Tuberculosis and leprosy are not allied diseases," because no leper ever died from leprosy, and unless he were carried off by febrile exhaustion, dysentery or some other concomitant affection, *tuberculosis* INvariably terminates the leper's suffering and lease of life; while it was in the viscera and tissues of *lepers, dead of tuberculosis* that LOOFT, ARNING, SIMPSON and others claim to have found a bacillus, which they called the specific microbe of lepra, but which it is more rational to conclude was a modified form of *B. tuberculosis*, which made up in number and sluggishness what it lost in size and activity from faulty nutrition, and the vital resistance of the body it inhabited. (c) page 96. "Because the *B. lepra* cannot be cultivated in bouillon or nutrient media outside the living body; it cannot be directly transferred from one animal to another by inoculation." Against this we have the Government inoculation of the convict KEANU; the excellent work done by ARNING, NEILSON, and DANIELSEN; the inoculation of that dearly good but unfortunate man Rev. Fr. DAMIEN; the indisputable results published by many other experimenters, myself among the number, and the confession at the late Buda-Pest Congress of Hygiene that bacilli belonging to one and the same family may and do assume a large variety of size, habits, virulence and activity in accordance to the nutriment they receive and the resistance of the blood of the animal they inhabit, without however losing their generic shape or form—except in size, habits, and number there is no difference in the *B. tuberculosis* and

* By Dr. G. A. Hansen and Dr. Carl Looff. Translated by Dr. Norman Walker.

the alleged B. lepra. (d) page 103 "In his Reconsideration of Leprosy Mr. W. Tebb utterly fails to produce conclusive evidence of the direct connection of leprosy with vaccination." Let Dr. WALKER carefully read—the cases published by Dr. GAIRDNER in the *British Medical Journal* (11-6-87); the evidence of mighty men such as MOURITZ, EMERSON, LUTZ, BAKWELL, FREELAND, SIR JONATHAN HUTCHINSON, SIR WILLIAM MOORE, TROUSSEAU and numberless others; Dr. M. D. MAKUNA's Medical Vaccination Census, and the evidence published by Mr. Tebb on pages 190, 191 to 196, 201, 103, 209, and 288 of authentic and convincing cases reported by Drs. CHUNDER GHOSE, R. S. CHEW, G. HOGGAN, G. THIN, DAUBLER, P. T. STUBBS, S. P. IMPRY and Bai Bahadur A. MITRA, Chief Medical Officer of Cashmir—every one of whom has had a large and varied experience of many years in leprosy, and whose experience is not confined to one solitary nation or district, as was that of the authors of the above work—and then ask Dr. WALKER if he will still persist in his contention that leprosy cannot be invaccinated or that he has the right to deliberately ignore the good results obtained in India.

Yours, &c., ROGER G. S. CHEW M. D. &c.,
Late Analyst to the Corporation of Calcutta.

CALCUTTA, 10th August 1895.

QUININE IN CHOLERA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—DR. HEHIR falls into some unconscious injustice in saying in your paper of the 16th August that he believes he was the first to shew that the use of quinine in cholera was a perfectly rational line of treatment. In his work on "Fever and Cholera," published in 1873, Dr. ALEX. SMITH has pages on the use of quinine in both cholera and sunstroke, and original suggestions on its prophylactic use in fever which bear on its use in the reactionary fever of cholera. The book was printed only for private circulation—and indeed I owe my own possession of a copy to Dr. SMITH's accidental identification of myself with the authorship of some article in a lay journal on the etiology of cholera, from which he had made quotations in his work—but on my shewing the book and Dr. SMITH's kindly letter which accompanied it to Dr. WALLER then a well-known independent practitioner in Calcutta he at once claimed the discovery for himself and told me he had published it in some periodical whose name I have forgotten.

Yours, &c., W. C. MADGE,

(As we understand it, Dr. Hehir claims not to have been the discoverer, of the use of quinine in cholera, but to have been the first to bring it into general use, as a routine course of treatment. The first time that this cinchona alkaloid was used in cholera was on the Indian Pilot Brig as far back as 1790, when the crude sulphate was first introduced.—E. J. M. R.)

THE MILK SUPPLY OF BRITISH TROOPS IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Now that there are a good number of cases of enteric fever and fatalities among officers too, it will be of some use to consider well how far a part this important article of food, for both the sick and healthy, plays in the causation of this frightful and lingering malady, which harasses longer than sunstroke, cholera and such

like suddenly fatal complaints. Pause in the rapid strides of bacteriology and look for a kinsman in the milk of life. Are there not many who, hating to take milk boiled, fancy that heat can not kill this mighty animalcule of milk and of the dirty water which is kindly added to it without much scruple by the "doodh-walla"—truly crying out "Doodh lethoo, doodh lethoo," i.e., no milk, no milk—and that, even after the original bacteria are annihilated, myriads of others are ready to take the place of the first culprit and murderer. Now let us consider how far the milkman (gladly and readily) takes a part in this murder for the sake of his pet bacteria, and this with almost complete immunity from the laws of both the humane bacteria and their European hosts. Now what are the steps taken to protect the Troops from this murder and are they effectual? Besides, the veracity of servants and the pass into barracks is there any other safeguard for a perfect and pure supply of milk to the Troops, even in hospitals which are like priests to the laymen? Are not the tricks of the milk trade well known in the past and present chronicles of milk diet and the number of lives saved thereby? Why do we wonder at "the horror of TOMMY ATKINS at the mere mention of the milk diet" and the Buddhist contempt for milk and its preparations? Cannot the sons of the mighty Bull, worshipped by all Asia, devise something for the supply of good milk to the sons of ALBION, at least, and thus shew their respect to their Lord Bull who was born in a manger near the stone trough, where DAVID used to water his sheep. I pity poor TOMMY ATKINS, whose wages are subtracted by the different arrangements of the regimental canteen, &c., and who, being thus kept in ignorance of the realities of life, yields his life for his loved and loving Queen and the country that lives by him, and him alone! May the authorities in power devise some effectual plan to obtain a pure supply of milk for both officers and soldiers in India is the wish.

Yours, &c., M. VERGHESSE.

CANNANORE, 7th August 1895.

REVIEW.

QUAIN'S ELEMENTS OF ANATOMY; Tenth Edition. VOL. III PART. II; THE NERVES. By PROFESSOR THANE: Edited by E. A. SCHAFER, F.R.S., and GEORGE D. THANE. Publishers, Messrs LONGMANS GREEN & Co., of London and New York: pp. 401. Price 9 Shillings.
